## 60V HIGH ACCURACY 1.5A BUCK/BOOST/BUCK-BOOST LED DRIVER CONVERTER WITH AEC-Q100

## Description

The ZXLD1374 is a 60V LED driver with integrated 1.5 A low side switch to drive high current LEDs. It is a multi-topology converter enabling it to operate in Buck, Boost and Buck-boost configurations; efficiently controlling the current of up to 16 -series connected LEDs.

The ZXLD1374 is a modified hysteretic converter using a patent pending control scheme providing high output current accuracy in all three topologies. High accuracy dimming is achieved through DC control and high frequency PWM control.

The ZXLD1374 uses two pins for fault diagnosis. A flag output highlights a fault, while the multi-level status pin gives further information on the exact fault.

The ZXLD1374 has been qualified to AEC-Q100 Grade 1 enabling operation in ambient temperatures from -40 to $+125^{\circ} \mathrm{C}$.

## Features

- 0.5\% Typical Output Current Accuracy
- 6.3 to 60 V Operating Voltage Range
- 1.5A Integrated Low Side Switch
- LED Driver Supports Buck, Boost and Buck-Boost Topologies
- Wide Dynamic Range Dimming
- 20:1 DC Dimming
- 1000:1 Dimming Range at 500 Hz
- Up to 1 MHz Switching
- High Temperature Control of LED Current Using TADJ
- AEC-Q100 Grade 1
- TSSOP-20EP: Available in "Green" Molding Compound (No Br, Sb ) with lead Free Finish/ RoHS Compliant
- Totally Lead-Free \& Fully RoHS Compliant (Notes 1 \& 2) - Halogen and Antimony Free. "Green" Device (Note 3)

## Pin Assignments

Notes: $\quad$ 1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS) \& 2011/65/EU (RoHS 2) compliant.
2. See http://www.diodes.com for more information about Diodes Incorporated's definitions of Halogen and Antimony free, "Green" and Lead-Free.
3. Halogen and Antimony free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total $\mathrm{Br}+\mathrm{Cl}$ ) and <1000ppm antimony compounds.

## Typical Applications Circuit

## Pin Descriptions

| Pin <br> Name | Pin | Type <br> (Note 4) | Function |
| :---: | :---: | :---: | :--- | :--- |
| ADJ | 1 | I | Adjust Input (for DC Output Current Control). <br> Connect to REF to set 100\% output current. <br> Drive with dc voltage (125mV $V_{\text {ADJ }}$ 2.5V) to adjust output current from 10\% to 200\% of set value. The <br> ADJ pin has an internal clamp that limits the internal node to less than 3V. This prevents the LED and power <br> switch from delivering too much current should ADJ get overdriven. |
| REF | 2 | O | Internal 1.25V reference voltage output |

Note: 4. Type refers to whether or not pin is an Input, Output, Input/Output or Power supply pin.

Absolute Maximum Ratings (Voltages to GND unless otherwise specified.)

| Symbol | Parameter | Rating | Unit |
| :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {IN }}$ | Input Supply Voltage Relative to GND ${ }^{\ddagger}$ | -0.3 to +65 | V |
| $\mathrm{V}_{\text {AUX }}$ | Auxiliary Supply Voltage Relative to GND ${ }^{\ddagger}$ | -0.3 to +65 | V |
| $V_{\text {ISM }}$ | Current Monitor Input Relative to GND ${ }^{\ddagger}$ | -0.3 to +65 | V |
| $\mathrm{V}_{\text {SENSE }}$ | Current Monitor Sense Voltage ( $\mathrm{V}_{1 N}-\mathrm{V}_{\text {ISM }}$ ) | -0.3 to +5 | V |
| $\mathrm{V}_{\text {LX }}$ | Low Side Switch Output Voltage to GND ${ }^{\ddagger}$ | -0.3 to +65 | V |
| lıx | Low Side Switch Continuous Output Current | 1.8 | A |
| Istatus | Status Pin Output Current | $\pm 1$ | mA |
| $V_{\text {FLAG }}$ | Flag Output Voltage to GND (Note 5) | -0.3 to +40 | V |
| $\mathrm{V}_{\text {PWM }}, \mathrm{V}_{\text {ADJ }}, \mathrm{V}_{\text {TADJ }}, \mathrm{V}_{\mathrm{GI}}$ | Other Input Pins to GND (Note 5) | -0.3 to +5.5 | V |
| ESD HBM | Human Body Model ESD Protection | 500 | V |
| ESD CDM | Charged Device Model ESD Protection | 1000 | V |
| TJ | Maximum Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {ST }}$ | Storage Temperature | -55 to +150 | ${ }^{\circ} \mathrm{C}$ |

Note: $\quad$ 5. For correct operation SGND and PGND should always be connected together.
These are stress ratings only. Operation outside the absolute maximum ratings may cause device failure.
Operation at the absolute maximum rating for extended periods may reduce device reliability.
Semiconductor devices are ESD sensitive and may be damaged by exposure to ESD events. Suitable ESD precautions should be taken when handling and transporting these devices.

## Package Thermal Data

Recommended Operating Conditions $\left(@ T_{\mathrm{A}}=+25^{\circ} \mathrm{C}\right.$, unless otherwise specified.)

| Symbol | Parameter | Performance/Comment | Min | Max | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Vin | Input Supply Voltage Range | Normal operation | 8 | 60 | V |
|  |  | Reduced performance operation (Note 7) | 6.3 |  |  |
| $V_{\text {Aux }}$ | Auxiliary Supply Voltage Range (Note 8) | Normal operation | 8 | 60 | V |
|  |  | Reduced performance operation (Note 7) | 6.3 |  |  |
| $V_{\text {SENSE }}$ | Differential Input Voltage | $\mathrm{V}_{\mathrm{VIN}}-\mathrm{V}_{\text {ISM }}$, with $0 \leq \mathrm{V}_{\text {ADJ }} \leq 2.5$ | 0 | 450 | mV |
| $V_{\text {LX }}$ | Low Side Switch Output Voltage |  |  | 60 | V |
| ILX | Low Side Switch Continuous Output Current |  |  | 1.5 | A |
| $V_{\text {ADJ }}$ | External DC Control Voltage Applied to ADJ Pin to Adjust Output Current | DC brightness control mode from $10 \%$ to $200 \%$ | 0.125 | 2.5 | V |
| Istatus | Status Pin Output Current |  |  | 100 | $\mu \mathrm{A}$ |
| IREF | Reference External Load Current | REF sourcing current |  | 1 | mA |
| $\mathrm{f}_{\text {Sw }}$ | Recommended Switching Frequency Range (Note 9) |  | 300 | 1000 | kHz |
| $\mathrm{V}_{\text {TADJ }}$ | Temperature Adjustment (TADJ) Input Voltage Range |  | 0 | $\mathrm{V}_{\text {REF }}$ | V |
| fpwm | Recommended PWM Dimming Frequency Range | To maintain 1000:1 resolution | 100 | 500 | Hz |
|  |  | To maintain 200:1 resolution | 100 | 1000 | Hz |
| tpWmH/L | PWM Pulse Width in Dimming Mode | PWM input high or low | 0.005 | 10 | ms |
| $\mathrm{V}_{\text {PWM }}$ | PWM Pin High Level Input Voltage |  | 2 | 5.5 | V |
| $\mathrm{V}_{\text {PWML }}$ | PWM Pin Low Level Input Voltage |  | 0 | 0.4 | V |
| $\mathrm{T}_{J}$ | Operating Junction Temperature Range |  | -40 | +125 | ${ }^{\circ} \mathrm{C}$ |
| GI | Gain Setting Ratio for Boost and Buck-Boost Modes | Ratio $=\mathrm{V}_{\mathrm{G}} / \mathrm{V}_{\text {ADJ }}$ | 0.20 | 0.50 |  |

Notes: $\quad$ 7. Device is guaranteed to have started up by 6.5 V and as such the minimum applied supply voltage has to be above 6.5 V (plus any noise margin). The ZXLD1374 will, however, continue to function when the input voltage is reduced from $\geq 8 \mathrm{~V}$ down to 6.3 V .
When operating with input voltages below 8 V the output current and device parameters may deviate from their normal values; and is dependent on power MOSFET switch, load and ambient temperature conditions. To ensure best operation in Boost and Buck-boost modes with input voltages, $\mathrm{V}_{\mathrm{IN}}$, between 6.5 and 12 V a suitable boot-strap network on $\mathrm{V}_{\text {Aux }}$ pin is recommended. Performance in Buck mode will be reduced at input voltages ( $\mathrm{V}_{\mathbf{I N}}$, $\mathrm{V}_{\text {AuX }}$ ) below 8 V . - A boot-strap network cannot be implemented in buck mode
8. $\mathrm{V}_{\text {AUX }}$ can be driven from a voltage higher than $\mathrm{V}_{\mathbb{I N}}$ to provide higher efficiency at low $\mathrm{V}_{\mathbb{I N}}$ voltages, but to avoid false operation; a voltage should not be applied to $\mathrm{V}_{\mathrm{AUX}}$ in the absence of a voltage at $\mathrm{V}_{\text {IN }}$.
9. The device contains circuitry to control the switching frequency to approximately 400 kHz . The maximum and minimum operating frequency is not tested.

| RDS(ON) | LX Pin MOSFET on Resistance | LLX $=1.5 \mathrm{~S}$ ( ton $<100 \mu \mathrm{~s}$ ) |  | 0.5 | 0.8 | $\Omega$ |
| tPDHL | Propagation Delay High-Low | $\begin{aligned} & V_{\text {SENSE }}=225 \mathrm{mV} \pm 30 \%, C_{L}=680 \mathrm{pF}, \\ & R_{L}=120 \Omega \end{aligned}$ |  | 86 |  | ns |
| tpdLH | Propagation Delay Low-High |  |  | 131 |  | ns |
| tLXR | LX Output Rise Time |  |  | 208 |  | ns |
| tLXF | LX Output Fall Time |  |  | 12 |  | ns |
| tstall | Time to assert 'STALL' flag and warning on STATUS output (Note 15) | LX low or high |  | 100 | 170 | $\mu \mathrm{s}$ |
| LED Thermal control circuit (TADJ) parameters |  |  |  |  |  |  |
| $V_{\text {TADJH }}$ | Upper Threshold Voltage | Onset of output current reduction ( $\mathrm{V}_{\text {TADJ }}$ falling) | 560 | 625 | 690 | mV |
| $V_{\text {TADJL }}$ | Lower Threshold Voltage | Output current reduced to < $10 \%$ of set value ( $\mathrm{V}_{\text {TADJ }}$ falling) | 380 | 440 | 500 | mV |
| ITADJ | TADJ Pin Input Current | $\mathrm{V}_{\text {TADJ }}=1.25 \mathrm{~V}$ |  |  | 1 | $\mu \mathrm{A}$ |

Notes: 12. Flag is asserted if $\mathrm{V}_{\text {SHP }}<2.5 \mathrm{~V}$ or $\mathrm{V}_{\text {SHP }}>3.5 \mathrm{~V}$
13. In the event of more than one fault/warning condition occurring, the higher priority condition will take precedence. E.g. 'Excessive coil current' and 'Out of regulation' occurring together will produce an output of 0.9 V on the STATUS pin. The voltage levels on the STATUS output assume the Internal regulator to be in regulation and $\mathrm{V}_{\text {ADJ }}<=\mathrm{V}_{\text {REF }}$. A reduction of the voltage on the STATUS pin will occur when the voltage on $\mathrm{V}_{\text {IN }}$ is near this is due to the feedback loop increasing the sense voltage.
14. With the device still in switching mode the LX pin has an over-voltage detection circuit connected to it with a resistance of approximately $1 \mathrm{M} \Omega$.
15. If $t_{\text {on }}$ exceeds $t_{\text {Stall }}$, LX turns off and then an initiate a restart cycle occurs. During this phase, ADJ is grounded internally and the SHP pin is switched to its nominal operating voltage, before operation is allowed to resume. Restart cycles will be repeated automatically until the operating conditions are such that normal operation can be sustained. If toff exceeds $\mathrm{t}_{\text {Stall }}$, the switch will remain off until normal operation is possible.

## Application Information

The ZXLD1374 is a high accuracy hysteretic inductive Buck/Boost/Buck-boost converter with an internal NMOS switch designed to be used for current-driving single or multiple series-connected LEDs. The device can be configured to operate in Buck, Boost, or Buck-boost modes by suitable configuration of the external components as shown in the schematics shown in the device operation description.

## Device Operation

## a) Buck Mode

The most simple Buck circuit is shown in Figure 26 LED current control in Buck mode is achieved by sensing the coil current in the sense resistor Rs, connected between the two inputs of a current monitor within the control loop block. An output from the control loop drives the input of a comparator which drives the gate of the internal NMOS switch transistor.

When the switch is on, current flows from $\mathrm{V}_{\mathrm{IN}}$, via Rs, LED, coil and switch to ground. This current ramps up until an upper threshold value is reached. At this point the switch is turned off and the current flows via Rs, LED, coil and D1 back to $\mathrm{V}_{\mathrm{IN}}$. When the coil current has ramped down to a lower threshold value the switch is turned on again and the cycle of events repeats, resulting in continuous oscillation.

The average current in the LED and coil is equal to the average of the maximum and minimum threshold currents. The ripple current (hysteresis) is equal to the difference between the thresholds.

The control loop maintains the average LED current at the set level by adjusting the thresholds continuously to force the average current in the coil to the value demanded by the voltage on the ADJ pin. This minimizes variation in output current with changes in operating conditions

The control loop also attempts to minimize changes in switching frequency by varying the level of hysteresis. The hysteresis has a defined minimum (typ $5 \%$ ) and a maximum (typ $20 \%$ ), the frequency may deviate from nominal in extreme conditions. Loop compensation is achieved by a single external capacitor C 1 , connected between SHP and SGND.

The control loop sets the duty cycle so that the sense voltage is

$$
V_{\text {SENSE }}=0.218\left(\frac{V_{\mathrm{ADJ}}}{\mathrm{~V}_{\mathrm{REF}}}\right)
$$

Therefore

$$
\text { LEED }=\left(\frac{0.218}{R_{S}}\right)\left(\frac{V_{A D J}}{V_{R E F}}\right) \text { (Buck mode) Equation } 1
$$

If the ADJ pin is connected to the REF pin, this simplifies to

$$
\text { LLED }=\left(\frac{0.218}{R_{S}}\right) \text { (Buck mode). }
$$

Figure 26 Buck Configuration

Figure 27 Operating Waveforms (Buck Mode)

A Product Line of Diodes Incorporated

## Application Information (cont.)

## a) Boost and Buck-Boost Modes

A basic ZXLD1374 application circuit for Buck-Boost and Boost modes is shown in Figure 28.
Control in Boost and Buck-boost mode is achieved by sensing the coil current in the series resistor Rs, connected between the two inputs of a current monitor within the control loop block.

An output from the control loop drives the input of a comparator which drives the gate of the internal NMOS switch transistor. In Boost and Buck-boost modes, when the switch is on, current flows from $\mathrm{V}_{\text {IN }}$, via Rs, coil and switch to ground. The switch current ramps up until an upper threshold value is reached (see Figure 29). At this point the switch is turned off and the drain voltage increases to either:

1) the LED chain voltage plus the forward voltage of D1 in Boost configuration,
or
2) the LED chain voltage plus the forward voltage of D1 plus VIN in Buck-boost configuration.

The inductor current flows via Rs, coil, D1 and LED back to $\mathrm{V}_{\mathrm{IN}}$ (Buck-boost mode), or GND (Boost mode). When the coil current has ramped down to a lower threshold value the switch is turned on again and the cycle of events repeats, resulting in continuous oscillation.

The feedback loop adjusts the NMOS switch duty cycle to stabilize the LED current in response to changes in external conditions, including input voltage and load voltage. Loop compensation is achieved by a single external capacitor C2, connected between SHP and SGND. Note that in reality, a load capacitor COUT is used, so that the LED current waveform shown is smoothed.

The average current in the coil is equal to the average of the maximum and minimum threshold currents and the ripple current (hysteresis) is equal to the difference between the thresholds. The average current in the LED, ILed, is always less than IRs. The feedback control loop adjusts the switch duty cycle, D , to achieve a set point at the sense resistor. This controls IRs.

During the interval toff, the coil current flows through D1 and the LED load.

During ton, the coil current flows through Q1, not the LEDs.
Therefore the set point is modified by D using a gating function to control ILED indirectly. In order to compensate internally for the effect of the gating function, a control factor, GI_ADJ is used. GI_ADJ is set by a pair of external resistors, $\mathrm{R}_{\mathrm{G} \mid 1}$ and $\mathrm{R}_{\mathrm{G} \mid 2}$. (Figure 28.)

This allows the sense voltage to be adjusted to an optimum level for power efficiency without significant error in the LED controlled current.

Figure 28 Boost and Buck-Boost Configuration

Figure 29 Operating Waveforms (Boost and Buck-Boost Modes)

## Application Information (cont.)

$$
\mathrm{GI} \_A D J=\left(\frac{\mathrm{RGI1}}{\mathrm{RGI1}+\mathrm{RGI2}}\right) \text { Equation } 2 \text { (Boost and Buck-Boost modes) }
$$

The control loop sets the duty cycle so that the sense resistor current is

$$
\mathrm{I}_{\mathrm{RS}}=\left(\frac{0.225}{\mathrm{RS}}\right)\left(\frac{\mathrm{GI} \_\mathrm{ADJ}}{1-\mathrm{D}}\right)\left(\frac{\mathrm{V}_{\mathrm{ADJ}}}{\mathrm{~V}_{\mathrm{REF}}}\right) \text { Equation } 3 \text { (Boost and Buck-Boost modes) }
$$

Irs equals the coil current. The coil is connected only to the switch and the schottky diode. The schottky diode passes the LED current. Therefore the average LED current is the coil current multiplied by the schottky diode duty cycle, 1-D.

$$
\text { LEED }=I_{R S}(1-D)=\left(\frac{0.225}{R_{S}}\right) G I_{-} A D J\left(\frac{V_{A D J}}{V_{R E F}}\right) \text { Equation } 4 \text { (Boost and Buck-Boost) }
$$

This shows that the LED current depends on the ADJ pin voltage, the reference voltage and 3 resistor values ( RS , RGI 1 and RGI ). It is independent of the input and output voltages.

If the ADJ pin is connected to the REF pin, this simplifies to

$$
\text { lLED }=\left(\frac{0.225}{R_{S}}\right) \mathrm{GI}_{-} A D J \text { (Boost and Buck-boost) }
$$

Now led is dependent only on the 3 resistor values.

Considering power dissipation and accuracy, it is useful to know how the mean sense voltage varies with input voltage and other parameters.

$$
\mathrm{V}_{\mathrm{RS}}=\mathrm{I}_{\mathrm{RS}} \mathrm{R}_{\mathrm{S}}=0.225\left(\frac{\mathrm{GI} \_\mathrm{ADJ}}{1-\mathrm{D}}\right)\left(\frac{\mathrm{V}_{\mathrm{ADJ}}}{\mathrm{~V}_{\mathrm{REF}}}\right) \text { Equation } 5 \text { (Boost and Buck-boost) }
$$

This shows that the sense voltage varies with duty cycle in Boost and Buck-boost configurations.

## Application Circuit Designs

External component selection is driven by the characteristics of the load and the input supply, since this will determine the kind of topology being used for the system. Component selection begins with the current setting procedure, the inductor/frequency setting selection. Finally after selecting the freewheeling diode and the output capacitor (if needed), the application section will cover the PWM dimming and thermal feedback The full procedure is greatly accelerated by the web Calculator spreadsheet, which includes fully automated component selection, and is available on the Diodes web site. However the full calculation is also given here.

Please note the following particular feature of the web Calculator. The GI ratio can be set for Automatic calculation, or it can be fixed at a chosen value. When optimizing a design, it is best first to optimize for the chosen voltage range of most interest, using the Automatic setting. In order to subsequently evaluate performance of the circuit over a wider input voltage range, fix the GI ratio in the Calculator input field, and then set the desired input voltage range

Some components depend upon the switching frequency and the duty cycle. The switching frequency is regulated by the ZXLD1374 to a large extent, depending upon conditions. This is discussed in a later paragraph dealing with coil selection.

## Application Information (cont.)

## Duty Cycle Calculation and Topology Selection

The duty cycle is a function of the input and output voltages. Approximately, the MOSFET switching duty cycle is

$$
\begin{array}{ll}
D_{\text {BUCK }} \approx \frac{V_{\text {OUT }}}{V_{\text {IN }}} & \text { for Buck } \\
D_{\text {BOOST }} \approx \frac{V_{\text {OUT }}-V_{\text {IN }}}{V_{\text {OUT }}} & \text { for Boost }
\end{array}
$$

Because D must always be a positive number less than 1 , these equations show that

$$
\begin{array}{ll}
V_{\text {OUT }}<V_{\text {IN }} & \text { for Buck (voltage step-down) } \\
V_{\text {OUT }}>V_{\text {IN }} & \text { for Boost (voltage step-up) } \\
V_{\text {OUT }}>\text { or }=\text { or }<V_{\text {IN }} & \text { for Buck-boost (voltage step-down or step-up) }
\end{array}
$$

This allows us to select the topology for the required voltage range.
More exact equations are used in the web Calculator. These are:

## Equation 6

$$
\mathrm{D}_{\mathrm{BB}} \approx \frac{\mathrm{~V}_{\text {OUT }}}{\mathrm{V}_{\mathrm{OUT}}+\mathrm{V}_{\text {IN }}} \quad \text { for Buck-Boost }
$$

The additional terms are relatively small, so the exact equations will only make a significant difference at lower operating voltages at the input and output, i.e. low input voltage or a small number of LEDs connected in series. The estimates of $\mathrm{V}_{\mathrm{F}}$ and $\mathrm{V}_{\mathrm{DSON}}$ depend on the coil current. The mean coil current, Icoil depends upon the topology and upon the mean terminal currents as follows:

$$
\begin{array}{ll}
I_{\text {COIL }}=I_{\text {LED }} & \text { for Buck } \\
I_{\text {COIL }}=I_{I N} & \text { for Boost } \\
I_{\text {COIL }}=I_{I N}+I_{\text {LED }} & \text { for Buck-Boost }
\end{array}
$$

lLED is the target LED current and is already known. IIN will be calculated with some accuracy later, but can be estimated now from the electrical power efficiency.

$$
\begin{aligned}
& D_{\text {BUCK }}=\frac{V_{\text {OUT }}+V_{F}+l_{\text {OUT }}\left(R_{S}+R_{\text {COIL }}\right)}{V_{\text {IN }}+V_{F}-V_{D S O N}} \quad \text { for Buck } \\
& D_{\text {BOOST }}=\frac{V_{O U T}-V_{I N}+l_{I N}\left(R_{S}+R_{\text {COIL }}\right)+V_{F}}{V_{O U T}+V_{F}-V_{D S O N}} \quad \text { for Boost } \quad \quad \text { Equation } 7 \\
& \mathrm{D}_{\mathrm{BB}}=\frac{\mathrm{V}_{\text {OUT }}+\mathrm{V}_{\mathrm{F}}+\left(\mathrm{ll}_{\mathrm{IN}}+\mathrm{l}_{\text {OUT }}\right)\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\text {COIL }}\right)}{V_{\text {OUT }}+\mathrm{V}_{\text {IN }}+\mathrm{V}_{\mathrm{F}}-\mathrm{V}_{\text {DSON }}} \quad \text { for Buck-Boost } \\
& \text { where } \quad V_{F} \quad=\text { schottky diode forward voltage, estimated for the expected coil current, IcoIL } \\
& V_{\text {DSON }}=\text { MOSFET drain source voltage in the ON condition (dependent on } R_{\text {DSON }} \text { and drain current }=I_{\text {COIL }} \text { ) } \\
& \mathrm{R}_{\text {coll }}=\mathrm{DC} \text { winding resistance of } \mathrm{L} 1
\end{aligned}
$$

## Application Information (cont.)

If the expected efficiency is roughly $90 \%$, the output power $P_{\text {out }}$ is $90 \%$ of the input power, $P_{I N}$, and the coil current is estimated as follows.

$$
\text { PoUt } \quad \approx 0.9 \mathrm{P}_{\mathrm{IN}}
$$

or

$$
\mathrm{I}_{\mathrm{LED}} \mathrm{~N} \mathrm{~V}_{\mathrm{LED}} \approx 0.9 \mathrm{I}_{\mathrm{IN}} \mathrm{~V}_{\mathrm{IN}}
$$

where N is the number of LEDs connected in series, and $V_{\text {LED }}$ is the forward voltage drop of a single LED at ILED.

So $\quad \mathrm{I}_{\mathrm{IN}} \approx \frac{\mathrm{ILED} \mathrm{N}_{\mathrm{VEED}}}{0.9 \mathrm{~V}_{\mathrm{IN}}}$

## Equation 9

Equation 9 can now be used to find Icoll in Equation 8, which can then be used to estimate the small terms in Equation 7. This completes the calculation of Duty Cycle and the selection of Buck, Boost or Buck-boost topology.

An initial estimate of duty cycle is required before we can choose a coil. In Equation 7, the following approximations are recommended:

$$
\begin{array}{ll}
\mathrm{V}_{\mathrm{F}} & =0.5 \mathrm{~V} \\
\mathrm{I}_{\mathrm{N}} \times\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\text {COIL }}\right) & =0.5 \mathrm{~V} \\
\mathrm{l}_{\text {OUT }} \times\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\text {COIL }}\right) & =0.5 \mathrm{~V} \\
\mathrm{~V}_{\text {DSON }} & =0.1 \mathrm{~V} \\
\left(\mathrm{I}_{\mathrm{N}}+\mathrm{I}_{\text {OUT }}\right)\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\text {COIL }}\right) & =1.1 \mathrm{~V}
\end{array}
$$

Then Equation 7 becomes

$$
\begin{array}{ll}
\mathrm{D}_{\mathrm{BUCK}} \approx \frac{\mathrm{~V}_{\mathrm{OUT}}+1}{\mathrm{~V}_{\text {IN }}+0.4} & \text { for Buck } \\
\mathrm{D}_{\mathrm{BOOST}} \approx \frac{\mathrm{~V}_{\mathrm{OUT}}-\mathrm{V}_{\text {IN }}+1}{\mathrm{~V}_{\mathrm{OUT}}+0.4} & \text { for Boost } \\
\mathrm{D}_{\mathrm{BB}} \approx \frac{\mathrm{~V}_{\text {OUT }}+1.6}{\mathrm{~V}_{\text {OUT }}+\mathrm{V}_{\text {IN }}+0.4} & \text { for Buck-Boost }
\end{array}
$$

## Setting the LED Current

The LED current requirement determines the choice of the sense resistor Rs. This also depends on the voltage on the ADJ pin and the voltage on the Gl pin, according to the topology required.

The ADJ pin may be connected directly to the internal 1.25 V reference $\left(\mathrm{V}_{\mathrm{REF}}\right)$ to define the nominal $100 \%$ LED current. The ADJ pin can also be driven with an external dc voltage between 125 mV and 2.5 V to adjust the LED current proportionally between $10 \%$ and $200 \%$ of the nominal value.

For a divider ratio GI_ADJ greater than 0.65 V , the ZXLD 1374 operates in Buck mode when $\mathrm{V}_{\mathrm{ADJ}}=1.25 \mathrm{~V}$. If $\mathrm{Gl} \_\mathrm{ADJ}$ is less than 0.65 V (typical), the device operates in Boost or buck-Boost mode, according to the load connection. This 0.65 V threshold varies in proportion to $\mathrm{V}_{\mathrm{ADJ}}$, i.e., the Buck mode threshold voltage is $0.65 \mathrm{~V}_{\mathrm{ADJ}} / 1.25 \mathrm{~V}$.

ADJ and GI are high impedance inputs within their normal operating voltage ranges. An internal 1.3 V clamp protects the device against excessive input voltage and limits the maximum output current to approximately $4 \%$ above the maximum current set by $\mathrm{V}_{\mathrm{REF}}$ if the maximum input voltage is exceeded.

A Product Line of Diodes Incorporated

## Application Information (cont.)

## Buck Topology

In Buck mode, Gl is connected to ADJ as in Figure 30 (for simplicity TADJ is not shown. However if not used should be connected to REF).

The LED current depends only upon $\mathrm{R}_{\mathrm{S}}, \mathrm{V}_{\mathrm{ADJ}}$ and $\mathrm{V}_{\text {REF }}$. From Equation 1 above,

$$
\text { RSBuck }=\left(\frac{0.218}{\text { LEED }}\right)\left(\frac{\mathrm{V}_{\mathrm{ADJ}}}{\mathrm{~V}_{\mathrm{REF}}}\right)
$$

Equation 10

If ADJ is directly connected to VREF, this becomes:

$$
\text { RSBuck }=\left(\frac{0.218}{\operatorname{lLED}}\right)
$$

## Boost and Buck-Boost Topology

In Boost and Buck-boost mode GI is connected to ADJ through a voltage divider as in figure 31 (for simplicity TADJ is not shown. However if not used should be connected to REF).
The LED current depends upon the resistors, $\mathrm{R}_{\mathrm{s}}, \mathrm{R}_{\mathrm{GI} 11}$, and $\mathrm{R}_{\mathrm{GI} 2}$ as in Equations 4 and 2 above. There is more than one degree of freedom. That is to say, there is not a unique solution. From Equation 4,

$$
\mathrm{RSBoostBB}=\left(\frac{0.225}{\mathrm{I}_{\mathrm{LED}}}\right) \mathrm{GI}_{-} \mathrm{ADJ}\left(\frac{\mathrm{~V}_{\mathrm{ADJ}}}{\mathrm{~V}_{\mathrm{REF}}}\right)
$$

## Equation 11

If ADJ is connected to REF, this becomes

$$
\text { RsBoostBB }=\left(\frac{0.225}{\text { LLED }}\right) \mathrm{GI}_{-} \mathrm{ADJ}
$$

GI_ADJ is given by Equation 2, repeated here for convenience:

$$
\mathrm{GI} \_\mathrm{ADJ}=\left(\frac{\mathrm{RGI} 1}{\mathrm{RGI} 1+\mathrm{RGI2}}\right)
$$

Figure 30 Buck Configuration

Figure 31 Boost and Buck-Boost Connection

Note that from considerations of ZXLD1374 input bias current, the recommended limits for $\mathrm{R}_{\mathrm{G} 11}$ are:

$$
22 \mathrm{k} \Omega<\mathrm{R}_{\mathrm{G} \mid 1}<100 \mathrm{k} \Omega
$$

## Equation 12

The additional degree of freedom allows us to select GI_ADJ within limits but this may affect overall performance a little. As mentioned above, the working voltage range at the GI pin is restricted. The permitted range of GI_ADJ in Boost or Buck-boost configuration is

$$
0.2<\text { GI_ADJ < } 0.5
$$

Equation 13
The mean voltage across the sense resistor is

$$
\mathrm{V}_{\mathrm{RS}}=\mathrm{I}_{\mathrm{COIL}} \mathrm{R}_{\mathrm{S}}
$$

## Equation 14

Note that if GI_ADJ is made larger, these equations show that $R_{S}$ is increased and $V_{R S}$ is increased. Therefore, for the same coil current, the dissipation in $R_{S}$ is increased. So, in some cases, it is better to minimize GI_ADJ. However, consider Equation 5. If ADJ is connected to REF, this becomes
$\mathrm{V}_{\mathrm{RS}}=0.225\left(\frac{\mathrm{GI} \text { _ADJ }}{1-\mathrm{D}}\right)$
This shows that $V_{R S}$ becomes smaller than 225 mV if $G I \_A D J<1-D$. If also $D$ is small, $V_{R S}$ can become too small. For example if $D=0.2$, and GI_ADJ is the minimum value of 0.2 , then $V_{R S}$ becomes $0.225^{*} 0.2 / 0.8=56.25 \mathrm{mV}$. This will increase the LED current error due to small offsets in the system, such as mV drop in the copper printed wiring circuit, or offset uncertainty in the ZXLD1371. If now, GI_ADJ is increased to 0.4 or $0.5, \mathrm{~V}_{\mathrm{RS}}$ is increased to a value greater than 100 mV .

## Application Information (cont.)

This will give small enough l led error for most practical purposes. Satisfactory operation will be obtained if $\mathrm{V}_{\mathrm{RS}}$ is more than about 80 mV . This means GI_ADJ should be greater than $\left(1-D_{\text {MIN }}\right) * 80 / 225=\left(1-D_{\text {MIN }}\right) * 0.355$.

There is also a maximum limit on $V_{R S}$ which gives a maximum limit for GI_ADJ. If $V_{R S}$ exceeds approximately 300 mV , or $133 \%$ of 225 mV , the STATUS output may indicate an over-current condition. This will happen for larger $D_{M A X}$. Therefore, together with the requirement of Equation 13 , the recommended range for GI_ADJ is

$$
0.355\left(1-\mathrm{D}_{\mathrm{MIN}}\right)<\mathrm{GI} \text { ADJ < } 1.33\left(1-\mathrm{D}_{\mathrm{MAX}}\right)
$$

## Equation 15

An optimum compromise for GI_ADJ has been suggested, i.e.

$$
\mathrm{GI}_{1} \mathrm{ADJ}_{\mathrm{AUTO}}=1-\mathrm{D}_{\mathrm{MAX}}
$$

## Equation 16

This value has been used for the "Automatic" setting of the web Calculator. If $1-D_{\text {MAX }}$ is less than 0.2 , then GI_ADJ is set to 0.2 . If $1-D_{\text {MAX }}$ is greater than 0.5 then GI_ADJ is set to 0.5 .

Once GI_ADJ has been selected, a value of RGI 1 can be selected from Equation 12. Then RGI2 is calculated as follows, rearranging Equation 2:

$$
\mathrm{R}_{\mathrm{Gl1}}=\mathrm{R}_{\mathrm{Gl1}}\left(\frac{1-\mathrm{GI}_{-} \mathrm{ADJ}}{\mathrm{GI} \mathrm{ADJ}^{\mathrm{ADJ}}}\right)
$$

Equation 17

For example to drive 12 LEDS at a current of 350 mA from a 12 V supply requires Boost configuration. Each LED has a forward voltage of 3.2 V at 350 mA , so Vout $=3.2 * 12=38.4 \mathrm{~V}$. From Equation 6, the duty cycle is approximately

$$
\frac{\left(\mathrm{V}_{\text {OUT }}-\mathrm{V}_{\text {IN }}\right)}{\mathrm{V}_{\text {OUT }}}=\frac{(38.4-12)}{38.4}=0.6875
$$

From Equation 16, we set GI_ADJ to $1-\mathrm{D}=0.3125$.

If $R_{G I 1}=33 \mathrm{k} \Omega$, then from Equation 17, $\mathrm{R}_{\mathrm{GI} 2}=33000$ * (1-0.3125)/0.3125=72.6k . Let us choose the preferred value $\mathrm{R}_{\mathrm{GI} 2}=75 \mathrm{k} \Omega$. Now GI_ADJ is adjusted to the new value, using Equation 2.

$$
\mathrm{Gl} \_\mathrm{ADJ}=\left(\frac{\mathrm{RGl} 1}{\mathrm{RGI} 1+\mathrm{RGI2}}\right)=\frac{33 \mathrm{k}}{33 \mathrm{k}+75 \mathrm{~K}}=0.305
$$

Now we calculate Rs from Equation 11. Assume ADJ is connected to REF.

$$
\text { RsBoostBB }=\left(\frac{0.225}{l_{\text {LED }}}\right) G I_{-} A D J\left(\frac{V_{\text {ADJ }}}{V_{\text {REF }}}\right)=\frac{0.225}{0.35} * 0.305=0.196 \Omega
$$

A preferredvalue of $R_{\text {SBoostBB }}=0.2 \Omega$ will give the desired LED current with an error of $2 \%$ due to the preferred value selection.
Table 1 shows typical resistor values used to determine the GI_ADJ ratio with E24 series resistors.
Table 1

| GI Ratio | RGI1 | RG2 |
| :---: | :---: | :---: |
| 0.2 | $30 \mathrm{k} \Omega$ | $120 \mathrm{k} \Omega$ |
| 0.25 | $33 \mathrm{k} \Omega$ | $100 \mathrm{k} \Omega$ |
| 0.3 | $39 \mathrm{k} \Omega$ | $91 \mathrm{k} \Omega$ |
| 0.35 | $30 \mathrm{k} \Omega$ | $56 \mathrm{k} \Omega$ |
| 0.4 | $100 \mathrm{k} \Omega$ | $150 \mathrm{k} \Omega$ |
| 0.45 | $51 \mathrm{k} \Omega$ | $62 \mathrm{k} \Omega$ |
| 0.5 | $30 \mathrm{k} \Omega$ | $30 \mathrm{k} \Omega$ |

This completes the LED current setting.

## Application Information (cont.)

## Inductor Selection and Frequency Control

The selection of the inductor coil, L1, requires knowledge of the switching frequency and current ripple, and also depends on the duty cycle to some extent. In the hysteretic converter, the frequency depends upon the input and output voltages and the switching thresholds of the current monitor. The peak-to-peak coil current is adjusted by the ZXLD1374 to control the frequency to a fixed value. This is done by controlling the switching thresholds within particular limits. This effectively much reduces the overall frequency range for a given input voltage range. Where the input voltage range is not excessive, the frequency is regulated to approximately 390 kHz . This is helpful in terms of EMC and other system requirements.

For larger input voltage variation, or when the choice of coil inductance is not optimum, the switching frequency may depart from the regulated value, but the regulation of LED current remains successful. If desired, the frequency can to some extent be increased by using a smaller inductor, or decreased using a larger inductor. The web Calculator will evaluate the frequency across the input voltage range and the effect of this upon power efficiency and junction temperatures.

Determination of the input voltage range for which the frequency is regulated may be required. This calculation is very involved, and is not given here. However the performance in this respect can be evaluated within the web Calculator for the chosen inductance.

The inductance is given as follows in terms of peak-to-peak ripple current in the coil, $\Delta \mathrm{I}_{\mathrm{L}}$ and the MOSFET on time, ton.

$$
\mathrm{L} 1=\left\{\mathrm{V}_{\mathrm{IN}}-\left(\mathrm{IIN}_{\mathrm{N}}+\mathrm{louT}\right)\left(\mathrm{R}_{\mathrm{DSON}}+\mathrm{RcOIL}^{2}+\mathrm{RS}_{\mathrm{S}}\right)\right\} \frac{\mathrm{tON}}{\Delta \mathrm{LL}} \quad \text { for Buck-Boost }
$$

Therefore In order to calculate L 1 , we need to find $\mathrm{I}_{\mathrm{N}}, \mathrm{t}_{\mathrm{ON}}$, and $\Delta \mathrm{I}_{\mathrm{L}}$. The effects of the resistances are small and will be estimated.
IN is estimated from Equation 9.
ton is related to switching frequency, f , and duty cycle, D , as follows:

$$
\operatorname{ton}=\frac{D}{f}
$$

## Equation 19

As the regulated frequency is known, and we have already found $D$ from Equation 7 or the approximation Equation 7b, this allows calculation of ton.

The ZXLD1374 sets the ripple current, $\Delta \mathrm{L}$, to between nominally $10 \%$ and $30 \%$ of the mean coil current, Icoll , which is found from Equation 8 . The device adjusts the ripple current within this range in order to regulate the switching frequency. We therefore need to use a $\Delta I_{L}$ value of $20 \%$ of $\mathrm{I}_{\text {coll }}$ to find an inductance which is optimized for the input voltage range. The range of ripple current control is also modulated by other circuit parameters as follows.

Equation 20

If ADJ is connected to REF, this simplifies to

Equation 20a
where $\Delta_{\text {LMID }}$ is the value we must use in Equation 18. We have now established the inductance value.

$$
\begin{aligned}
& \Delta \text { llmax }=0.3 \frac{1-\mathrm{D}}{\mathrm{GI} \_ \text {ADJ }} \mathrm{I}^{\text {coil }} \\
& \Delta \mathrm{L} \mathrm{LMIN}=0.1 \frac{1-\mathrm{D}}{\mathrm{GI} \text { _ADJ }} \text { ICOIL } \\
& \Delta \mathrm{I}_{\mathrm{LMID}}=0.2 \frac{1-\mathrm{D}}{\text { GI_ADJ }} \mathrm{I}_{\text {COIL }}
\end{aligned}
$$

$$
\begin{aligned}
& \Delta \operatorname{lLMAX}=\left\{0.06+0.24\left(\frac{V_{\text {ADJ }}}{V_{\text {REF }}}\right)\right\} \frac{1-\mathrm{D}}{G I_{-} \text {ADJ }} \text { lcoIL } \\
& \Delta \operatorname{lLMIN}=\left\{0.02+0.08\left(\frac{\mathrm{~V}_{\text {ADJ }}}{\mathrm{V}_{\text {REF }}}\right)\right\} \frac{1-\mathrm{D}}{\mathrm{GI} \text { _ADJ }} \text { IcoIL } \\
& \Delta \operatorname{lLMID}=\left\{0.04+0.16\left(\frac{\mathrm{~V}_{\text {ADJ }}}{\mathrm{V}_{\text {REF }}}\right)\right\} \frac{1-\mathrm{D}}{\mathrm{GI} \_ \text {ADJ }} \mathrm{I}_{\mathrm{COIL}}
\end{aligned}
$$

$$
\begin{aligned}
& \mathrm{L} 1=\left\{\mathrm{V}_{\text {IN }}-\mathrm{N} \mathrm{~V}_{\text {LED }}-\text { loUT }\left(\mathrm{R}_{\text {DSON }}+\mathrm{R}_{\text {COIL }}+\mathrm{R}_{\mathrm{S}}\right)\right\} \frac{\text { ton }}{\Delta \mathrm{LL}} \quad \text { for Buck } \\
& \mathrm{L} 1=\left\{\mathrm{V}_{\mathrm{IN}}-\mathrm{I}_{\mathrm{IN}}\left(\mathrm{R}_{\mathrm{DSON}}+\mathrm{R}_{\text {coil }}+\mathrm{RS}_{\mathrm{S}}\right)\right\} \frac{\mathrm{tON}}{\Delta \mathrm{IL}} \quad \text { for Boost }
\end{aligned}
$$

## Application Information (cont.)

The chosen coil should saturate at a current greater than the peak sensed current. This saturation current is the DC current for which the inductance has decreased by $10 \%$ compared to the low current value.

Assuming $\pm 10 \%$ ripple current, we can find this peak current from Equation 8, adjusted for ripple current:

```
ICOILPEAK= 1.1 lLED for Buck
COILPEAK = 1.1 I INMAX for Boost
Equation 21
ICOILPEAK = 1.1 l INMAX + I IED for Buck-boost
```

where $\mathrm{I}_{I N M A X}$ is the value of $\mathrm{I}_{\mathbb{I}}$ at minimum $\mathrm{V}_{\mathbb{I N}}$.
The mean current rating is also a factor, but normally the saturation current is the limiting factor.
The following websites may be useful in finding suitable components
www.coilcraft.com
www.niccomp.com
www.wuerth-elektronik.de

## Diode Selection

For maximum efficiency and performance, the rectifier (D1) should be a fast low capacitance Schottky diode* with low reverse leakage at the maximum operating voltage and temperature. The Schottky diode also provides better efficiency than silicon PN diodes, due to a combination of lower forward voltage and reduced recovery time.

It is important to select parts with a peak current rating above the peak coil current and a continuous current rating higher than the maximum output load current. In particular, it is recommended to have a voltage rating at least $15 \%$ higher than the maximum LX voltage to ensure safe operation during the ringing of the switch node and a current rating at least $10 \%$ higher than the average diode current. The power rating is verified by calculating the power loss through the diode.

The higher forward voltage and overshoot due to reverse recovery time in silicon diodes will increase the peak voltage on the LX pin. If a silicon diode is used, care should be taken to ensure that the total voltage appearing on the LX pin, including supply ripple, does not exceed the specified maximum value.
*A suitable Schottky diode would be PDS3100 (Diodes Inc).

## Output Capacitor

An output capacitor may be required to limit interference or for specific EMC purposes. For Boost and Buck-boost regulators, the output capacitor provides energy to the load when the freewheeling diode is reverse biased during the first switching subinterval. An output capacitor in a Buck topology will simply reduce the LED current ripple below the inductor current ripple. In other words, this capacitor changes the current waveform through the LED(s) from a triangular ramp to a more sinusoidal version without altering the mean current value.

In all cases, the output capacitor is chosen to provide a desired current ripple of the LED current (usually recommended to be less than $40 \%$ of the average LED current).

## Buck:

$$
\text { CoUTPUT }=\frac{\Delta L_{\text {L-PP }}}{8 \times x_{S W} \times{ }_{\text {rLED }} \times \Delta I_{\text {LED-PP }}}
$$

## Boost and Buck-boost

$$
\text { CoUTPUT }=\frac{\text { DxlLED }}{\mathrm{fSW}^{\times} \times \mathrm{r}_{\text {LED }} \times \Delta \text { ILED-PP }}
$$

where:

- $\quad \Delta \mathrm{I}_{\mathrm{L}}$ is the ripple of the inductor current, usually $\pm 20 \%$ of the average sensed current
- $\quad \Delta_{\text {LED }}$ is the ripple of the LED current, it should be $<40 \%$ of the LEDs average current
- $\quad f_{s w}$ is the switching frequency (from graphs and calculator)
- $\quad r_{\text {LED }}$ is the dynamic resistance of the LEDs string ( $n$ times the dynamic resistance of the single LED from the datasheet of the LED manufacturer).

## ZXLD1374

## Application Information (cont.)

## Output Capacitor (cont.)

The output capacitor should be chosen to account for derating due to temperature and operating voltage. It must also have the necessary RMS current rating. The minimum RMS current for the output capacitor is calculated as follows:

## Buck

$$
\text { loutput-RMS }=\frac{\text { LEED-PP }}{\sqrt{12}}
$$

## Boost and Buck-Boost

$$
\text { loutput-RMs }=\text { LLED } \sqrt{\frac{\mathrm{D}_{\text {MAX }}}{1-\mathrm{D}_{\text {MAX }}}}
$$

Ceramic capacitors with X7R dielectric are the best choice due to their high ripple current rating, long lifetime, and performance over the voltage and temperature ranges.

## Input Capacitor

The input capacitor can be calculated knowing the input voltage ripple $\Delta \mathrm{V}_{\mathrm{IN} \text {-PP }}$ as follows:

## Buck

$$
C_{I N}=\frac{D x(1-D) \times \mathrm{I}_{\text {LED }}}{f_{S W} \times \Delta V_{I N-P P}} \quad \text { use } D=0.5 \text { as worst case }
$$

## Boost

$$
\mathrm{C}_{\mathrm{IN}}=\frac{\Delta \mathrm{L}_{\mathrm{L}-\mathrm{PP}}}{8 \mathrm{Xf}_{\mathrm{SW}} \times \Delta \mathrm{V}_{\mathrm{IN}-\mathrm{PP}}}
$$

## Buck-boost

$$
\mathrm{C}_{\mathrm{IN}}=\frac{\mathrm{DxILED}^{f_{S W} \times \Delta V_{\text {IN-PP }}} \quad \text { use } \mathrm{D}=\mathrm{D}_{\text {MAX }} \text { as worst case }}{}
$$

The minimum RMS current for the output capacitor is calculated as follows:
Buck

$$
I_{C I N-R M S}=I_{\text {LED }} x \sqrt{D x(1-D)} \quad \text { use } D=0.5 \text { as worst case }
$$

Boost

$$
\operatorname{ICIN-RMS}=\frac{\text { LL-PP }}{\sqrt{12}}
$$

## Buck-Boost

$$
I_{C I N-R M S}=\operatorname{ILED} \text { X } \sqrt{\frac{D}{1-D}} \quad \text { use } D=D_{M A X} \text { as worst case }
$$

A Product Line of Diodes Incorporated

ZFIEX

## Application Information (cont.)

## Over-Temperature Shutdown

The ZXLD1374 incorporates an over-temperature shutdown circuit to protect against damage caused by excessive die temperature. A warning signal is generated on the STATUS output when die temperature exceeds $+125^{\circ} \mathrm{C}$ nominal and the output is disabled when die temperature exceeds $150^{\circ} \mathrm{C}$ nominal. Normal operation resumes when the device cools back down to $+125^{\circ} \mathrm{C}$.

## Flag/Status Outputs

The FLAG/STATUS outputs provide a warning of extreme operating or fault conditions. FLAG is an open-drain logic output, which is normally off, but switches low to indicate that a warning, or fault condition exists. STATUS is a DAC output, which is normally high ( 4.5 V ), but switches to a lower voltage to indicate the nature of the warning/fault.

Table 2
Conditions monitored, the method of detection and the nominal STATUS output voltage are given in the following table (Note 15):

| Warning/Fault Condition | Severity <br> (Note 16) | Monitored <br> Parameters | FLAG | Nominal STATUS Voltage |
| :---: | :---: | :---: | :---: | :---: |

Notes:
15. These STATUS pin voltages apply for an input voltage, $\mathrm{V}_{\mathbb{I N}}$, of $7.5 \mathrm{~V}<\mathrm{V}_{\mathbb{I N}}<60 \mathrm{~V}$. Below 7.5 V the STATUS pin voltage levels reduce and therefore may not report the correct status. For $6.3 \mathrm{~V}<\mathrm{V}_{\mathbb{I N}}<7.5 \mathrm{~V}$ the flag pin still reports an error by going low. At low $\mathrm{V}_{\text {IN }}$ in Boost and Buck-boost modes an overcurrent status may be indicated when operating at high boost ratios - this due to the feedback loop increasing the sense voltage.
16. Severity 1 denotes lowest severity.
17. This warning will be indicated if the output power demand is higher than the available input power; the loop may not be able to maintain regulation.
18. This warning will be indicated if the gate pin stays at the same level for greater than $100 \mu \mathrm{~s}$ (e.g. the output transistor cannot pass enough current to reach the upper switching threshold).

A Product Line of Diodes Incorporated

ZFIEX

## Application Information (cont.)

Figure 32 Status Levels
In the event of more than one fault/warning condition occurring, the higher severity condition will take precedence. E.g. 'Excessive coil current' and 'Out of regulation' occurring together will produce an output of 0.9 V on the STATUS pin.

If $\mathrm{V}_{\text {ADJ }}>1.7 \mathrm{~V}$, $\mathrm{V}_{\text {SENSE }}$ may be greater than the excess coil current threshold in normal operation and an error will be reported. Hence, STATUS and FLAG are only guaranteed for $\mathrm{V}_{\mathrm{ADJ}}<=\mathrm{V}_{\text {REF }}$.

Diagnostic signals should be ignored during the device start - up for $100 \mu \mathrm{~s}$. The device start up sequence will be initiated both during the first power on of the device or after the PWM signal is kept low for more than 15 ms , initiating the standby state of the device.

In particular, during the first $100 \mu$ s the diagnostic is signaling an over-current then an out-of-regulation status. These two events are due to the charging of the inductor and are not true fault conditions.

Figure 33 Diagnostic During Start-Up

## Application Information (cont.)

## Reduced Input Voltage Operation

To facilitate operation in applications that have large transient reductions in system supply voltage, the ZXLD1374 is capable of operating down to input voltages as low as 6.3 V . Care must be taken when operating at these lower supply voltages to ensure that the internal MOSFET is correctly enhanced and that the boosting ratio is not increased to excessive amounts where both the duty cycle and peak-switch current limits are not exceeded. The device will operate down to 6.3 V , but for reliable start up $\mathrm{V}_{\mathrm{IN}}$ must be higher than 6.5 V plus any margins for any noise that may occur on the supply lines

In Buck-boost and Boost modes (most common topologies for applications likely to require transient operation down to supply voltages approaching 6V) as the input voltage reduces then the peak switch current will increase the ZXLD1374 compensates for this by allowing the sense voltage to increase while maintaining regulation of the LED current. However if the boost ratio (switch output voltage/input voltage) is increased too much then the sense voltage could be increased too much causing an over-current flag to be triggered and/or loss of regulation.

In addition to this, increased power dissipation will occur in the internal MOSFET switch. One way of overcoming this is to apply a boot-strap network to the $\mathrm{V}_{\text {AUX }}$ pin - see next section.

If the ZXLD1374 is used in buck mode at low voltages then the boot-strap network cannot be implemented and some loss of regulation may occur at input voltages approaching 6V driving 1 LED.

When using the ZXLD1374 in applications with transient input voltage excursions we recommend using the web calculator to optimize operation over the normal operating band. Then change the input range to include the transient excursion while keeping the optimized component selection to check expected function during the transient input voltage conditions

## Boosting $\mathbf{V}_{\text {Aux }}$ Supply Voltage in Boost and Buck-Boost Mode

A boot-strap boosting technique can be used to increase the gate drive voltage at low input voltage. See figure 34 for circuit diagram. This can be particularly important for extended use at low input voltages as this is when the switch current will be at its greatest - resulting in greatest heat generation within the MOSFET.

Figure 34. Bootstrap Circuit for Boost and Buck-Boost Low Voltage Operations

The Bootstrap circuit guarantees that the MOSFET is fully enhanced reducing both the power dissipation and the risk of thermal runaway of the MOSFET itself. The bootstrap circuit consists of an extra diode D2 and decoupling capacitor C 8 which are used to generate a boosted voltage at $\mathrm{V}_{\text {Aux }}$. This enables the device to operate with full output current when $\mathrm{V}_{\mathbb{I}}$ is at the minimum value of 6.3 V . The resistor R 13 can be used to limit the current in the bootstrap circuit in order to reduce the impact of the circuit itself on the LED accuracy. A typical value would be 100 ohms. The impact on the LED current is usually a decrease of maximum 5\% compared to the nominal current value set by the sense resistor.

The Zener diode may be used to limit the voltage on the $\mathrm{V}_{\mathrm{Aux}}$ pin to less than 60 V .
Due to the increased number of components and the loss of current accuracy, the bootstrap circuit is recommended only when the system has to operate continuously in conditions of low input voltage (between 6.3 and 8 V ) and high load current.
If lower transient voltages are expected then the ZXLD1371 LED Driver-controller could be used, whose input voltage extends down to 5 V .

## Application Information (cont.)

## Over-Voltage Protection

The ZXLD1374 is inherently protected against open-circuit load when used in Buck configuration. However care has to be taken with opencircuit load conditions in Buck-boost or Boost configurations. This is because in these configurations there is only an over-voltage FLAG but no internal open-circuit protection mechanism for the internal MOSFET. In this case an Over-Voltage-Protection (OVP) network should be provided to the MOSFET to avoid damage due to open circuit conditions. This is shown in Figure 35 below, highlighted in the dotted blue box.

Figure 35 OVP Circuit

The zener voltage is determined according to: $V_{Z}=V_{\text {LEDMAX }}+10 \%$. If the $L X$ pin voltage exceeds $V_{z}$ the gate of MOSFET Q1 will rise turning $Q 1$ on. This will pull the PWM pin low and disable the LX output until the voltage on the LX falls below Vz . If the LX pin remains above $\mathrm{V}_{Z}$ for longer than 20 ms then the ZXLD1374 will enter into a shutdown state.

Care should be taken such that the maximum gate voltage of the Q1 MOSFET is not exceeded.
An alternative solution for OVP function is to use the diagnostic section of the ZXLD1374 to initiate the disabling of the LX pin. For example, a microcontroller could be used to respond to the FLAG and the status pins, and if an over-voltage state is indicated, the microcontroller could switch the device off by pulling the PWM signal low.

## Application Information (cont.)

## LED Current Dimming

The ZXLD1374 has 3 dimming methods for reducing the average LED current

1. Analog dimming using the ADJ pin
2. PWM dimming using the PWM pin
3. Analog dimming for thermal protection using the TADJ pin.

## Analog Dimming

The ZXLD1374 has a clamp on the ADJ pin to prevent over-driving of the LED current which results in the maximum voltage being applied to internal circuitry is the reference voltage. This provides a 10:1 dynamic range of dc LED current adjustment.

The equation for DC dimming of the LED current is approximately:

$$
\text { LLED_DIM }_{-}=\text {lLED_NOM }_{-}\left(\frac{\mathrm{V}_{\text {ADJ }}}{\mathrm{V}_{\mathrm{REF}}}\right)
$$

Where
lLED_DIM is the dimmed LED current
$I_{\text {LED_NOM }}$ is the LED current with $\mathrm{V}_{\text {ADJ }}=1.25 \mathrm{~V}$
One consequence of DC dimming is that as the ADJ pin voltage is reduced the sense voltage will also be reduced which has an impact on accuracy and switching frequency especially at lower ADJ pin voltages.

Figure 36 LED Current and Switching Frequency vs. ADJ Voltage

A Product Line of Diodes Incorporated

ZFIEX

## ZXLD1374

## Application Information (cont.)

## PWM Output Current Control \& Dimming

The ZXLD1374 has a dedicated PWM dimming input that allows a wide dimming frequency range from 100 Hz to 1 kHz with $1000: 1 \mathrm{resolution}$; however higher dimming frequencies can be used - at the expense of dimming dynamic range and accuracy.
Typically, for a PWM frequency of 1 kHz , the error on the current linearity is lower than $5 \%$; in particular the accuracy is better than $1 \%$ for PWM from $5 \%$ to $100 \%$. This is shown in the graph below for Buck mode:

Figure 37 LED Current Linearity and Accuracy with PWM Dimming at 1 kHz

For a PWM frequency of 100 Hz , the error on the current linearity is lower than $2.5 \%$; it becomes negligible for PWM greater than $5 \%$. This is shown in the graph below:

Figure 38 LED Current Linearity and Accuracy with PWM Dimming at 100 Hz

## Application Information (cont.)

## PWM Output Current Control \& Dimming (cont.)

The PWM pin is designed to be driven by both 3.3 V and 5 V logic levels. It can be driven also by an open drain/collector transistor. In this case the designer can either use the internal pull-up network or an external pull-up network in order to speed-up PWM transitions, as shown in the Boost/ Buck-Boost section.

LED current can be adjusted digitally, by applying a low frequency PWM logic signal to the PWM pin to turn the controller on and off. This will produce an average output current proportional to the duty cycle of the control signal. During PWM operation, the device remains powered up and only the output switch is gated by the control signal.

The PWM signal can achieve very high LED current resolution. In fact, dimming down from $100 \%$ to 0 , a minimum pulse width of $5 \mu \mathrm{~s}$ can be achieved resulting in very high accuracy. While the maximum recommended pulse is for the PWM signal is 10 ms .

Figure 41 PWM Dimming Minimum and Maximum Pulse

## Standby Mode

The device can be put in standby by taking the PWM pin to a voltage below 0.4 V for a time exceeding 20 ms (15ms nominal). In the shutdown state, most of the circuitry inside the device is switched off and residual quiescent current will be typically $90 \mu \mathrm{~A}$. In particular, the Status pin will go down to GND while the FLAG and REF pins will stay at their nominal values.

Figure 42 Stand-By State from PWM Signal

## Application Information (cont.)

## Thermal Control of LED Current

For thermal control of the LEDs, the ZXLD1371 monitors the voltage on the TADJ pin and reduces output current if the voltage on this pin falls below 625 mV . An external NTC thermistor and resistor can therefore be connected as shown below to set the voltage on the TADJ pin to 625 mV at the required temperature threshold. This will give $100 \%$ LED current below the threshold temperature and a falling current above it as shown in the graph. The temperature threshold can be altered by adjusting the value of Rth and/or the thermistor to suit the requirements of the chosen LED.

The Thermal Control feature can be disabled by connecting TADJ to REF.
Here is a simple procedure to design the thermal feedback circuit:

1. Select the temperature threshold $\mathrm{T}_{\text {THRESHOLD }}$ at which the current must start to decrease
2. Select the Thermistor TH 1 (both resistive value at $+25^{\circ} \mathrm{C}$ and beta)
3. Select the value of the resistor $\mathrm{R}_{\mathrm{TH}}$ as $\mathrm{R}_{\mathrm{TH}}=\mathrm{TH}_{1}$ at $\mathrm{T}_{\text {THRESHoLd }}$

Figure 43 Thermal Feedback Network

For example,

1. Temperature threshold $\mathrm{T}_{\text {THRESHOLD }}=+70^{\circ} \mathrm{C}$
2. $\mathrm{TH} 1=10 \mathrm{k} \Omega$ at $25^{\circ} \mathrm{C}$ and beta $=3500 \rightarrow \mathrm{TH} 1=3.3 \mathrm{k} \Omega$ at $+70^{\circ} \mathrm{C}$
3. $\mathrm{R}_{\mathrm{TH}}=\mathrm{TH} 1$ at $\mathrm{T}_{\text {THRESHOLD }}=3.3 \mathrm{k} \Omega$

## Application Information (cont.)

## PCB Layout Considerations

PCB layout is a fundamental activity to get the most of the device in all configurations. In the following section it is possible to find some important insight to design with the ZXLD1374 both in Buck and Buck-Boost/Boost configurations.

Figure 44 Circuit Layout

Here are some considerations useful for the PCB layout:

- In order to avoid ringing due to stray inductances, the inductor L1, the anode of D1 and the LX pin should be placed as close together as possible.
- The shaping capacitor C1 is fundamental for the stability of the control loop. To this end it should be placed no more than 5 mm from the SHP pin.
- Input voltage pins, $\mathrm{V}_{\mathbb{N}}$ and $\mathrm{V}_{\mathrm{AUX}}$, need to be decoupled. It is recommended to use two ceramic capacitors of $2.2 \mu \mathrm{~F}, \mathrm{X} 7 \mathrm{R}, 100 \mathrm{~V}$ ( C 3 and C4). In addition to these capacitors, it is suggested to add two ceramic capacitors of $1 \mu \mathrm{~F}, \mathrm{X} 7 \mathrm{R}, 100 \mathrm{~V}$ each (C2, C8), as well as a further decoupling capacitor of 100 nF close to the $\mathrm{V}_{\mathbb{N}} / \mathrm{V}_{\text {AUX }}$ pins (C9) the device is used in Buck mode, or can be driven from a separate supply.
- Ensure that there is a large enough thermal mass to keep the thermal impedance between junction and ambient to keep the ZXLD1374 junction temperature below $+125^{\circ} \mathrm{C}$. On a 2 layer board this means putting enough vias from the landing pad of the TSSOP-20EP exposed pad through to the bottom layer.

## Application Information (cont.)

### 1.5A Buck LED Driver

In this application example, ZXLD1374 is connected as a Buck LED driver with schematic and parts list shown below. The LED driver is able to deliver 1.5A of LED current to single or multiple LEDs in series with input voltage ranged from 10 V to 50 V . In order to achieve high efficiency under high LED current, Super Barrier Rectifier (SBR) with low forward voltage is used as free wheeling rectifier.

With only a few extra components, the ZXLD1374 LED driver is able to deliver LED power of greater than 60W. This is suitable for applications which require high LED power likes high power down lighting, wall washer, automotive LED lighting etc.

## 350mA Boost LED Driver

In this application example, ZXLD1374 is connected as a Boost LED driver with schematic and parts list shown below. The LED driver is able to deliver 350 mA of LED current into 12 high brightness LED with input voltage ranged from 16 V to 28 V .

Overall high efficiency of $92 \%+$ make it ideal for applications likes solar LED street lighting and general LED illuminations.

## 350mA Buck-boost LED driver

In this application example, ZXLD1374 is connected as a Buck-boost LED driver with schematic and parts list shown below. The LED driver is able to deliver 350 mA of LED current into $4 / 5$ high brightness LED with input voltage ranged from 7 V to 20 V . In order to increase the driving voltage level for the internal MOSFET during low voltage input, bootstrap circuit formed by R6 D2 and C6 are used to supply higher voltage to the VAUX pin.

Since the Buck-boost LED driver can handle an input voltage range below and above the LED voltage, this versatile input voltage range makes it ideal for automotive lighting applications.

## LIFE SUPPORT

Diodes Incorporated products are specifically not authorized for use as critical components in life support devices or systems without the express written approval of the Chief Executive Officer of Diodes Incorporated. As used herein:
A. Life support devices or systems are devices or systems which:

1. are intended to implant into the body, or
2. support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in significant injury to the user.
B. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or to affect its safety or effectiveness.

Customers represent that they have all necessary expertise in the safety and regulatory ramifications of their life support devices or systems, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of Diodes Incorporated products in such safety-critical, life support devices or systems, notwithstanding any devices- or systems-related information or support that may be provided by Diodes Incorporated. Further, Customers must fully indemnify Diodes Incorporated and its representatives against any damages arising out of the use of Diodes Incorporated products in such safety-critical, life support devices or systems.
