

Description

The AP63200Q/AP63201Q/AP63203Q/AP63205Q is an automotive-compliant, 2A, synchronous buck converter with a wide input voltage range of 3.8V to 32V. The device fully integrates a 125mΩ high-side power MOSFET and a 68mΩ low-side power MOSFET to provide high-efficiency step-down DC-DC conversion.

The AP63200Q/AP63201Q/AP63203Q/AP63205Q device is easily used by minimizing the external component count due to its adoption of peak current mode control along with its integrated loop compensation network.

The AP63200Q/AP63201Q/AP63203Q/AP63205Q design is optimized for Electromagnetic Interference (EMI) reduction. The device has a proprietary gate driver scheme to resist switching node ringing without sacrificing MOSFET turn-on and turn-off times, which reduces high-frequency radiated EMI noise caused by MOSFET switching. The AP63200Q/AP63203Q/AP63205Q also features Frequency Spread Spectrum (FSS) with a switching frequency jitter of ±6%, which reduces EMI by not allowing emitted energy to stay in any one frequency for a significant period of time.

The device is available in a TSOT26 package.

Features

- AEC-Q100 Qualified for Automotive Applications
 - Device Temperature Grade 1: -40°C to +125°C T_A Range
- VIN: 3.8V to 32V
- Output Voltage (V_{OUT})
 - 0.8V to VIN: AP63200Q and AP63201Q
 - Fixed 3.3V: AP63203Q
 - Fixed 5V: AP63205Q
- 2A Continuous Output Current
- 0.8V ± 1% Reference Voltage
- 22μA Low Quiescent Current (Pulse Frequency Modulation)
- Switching Frequency
 - 500kHz: AP63200Q and AP63201Q
 - 1100kHz: AP63203Q and AP63205Q
- Supports Pulse Frequency Modulation (PFM)
 - AP63200Q, AP63203Q, and AP63205Q
 - Up to 88% Efficiency at 5mA Light Load
- Pulse Width Modulation (PWM) Regardless of Output Load
 - AP63201Q
- Proprietary Gate Driver Design for Best EMI Reduction
- Frequency Spread Spectrum (FSS) to Reduce EMI
 - AP63200Q, AP63203Q, and AP63205Q
- Low-Dropout (LDO) Mode
- Precision Enable Threshold to Adjust UVLO
- Protection Circuitry
 - Undervoltage Lockout (UVLO)
 - Output Overvoltage Protection (OVP)
 - Cycle-by-Cycle Peak Current Limit
 - Thermal Shutdown
- **Totally Lead-Free & Fully RoHS Compliant (Notes 1 & 2)**
- **Halogen and Antimony Free. "Green" Device (Note 3)**
- **The AP63200Q, AP63201Q, AP63203Q, and AP63205Q are suitable for automotive applications requiring specific change control; these parts are AEC-Q100 qualified, PPAP capable, and manufactured in IATF 16949 certified facilities.**
<https://www.diodes.com/quality/product-definitions/>

- Notes:
1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS), 2011/65/EU (RoHS 2) & 2015/863/EU (RoHS 3) compliant.
 2. See <https://www.diodes.com/quality/lead-free/> for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
 3. Halogen- and Antimony-free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total Br + Cl) and <1000ppm antimony compounds.

Pin Descriptions

Pin Name	Pin Number	Function
FB	1	Feedback sensing terminal for the output voltage. Connect this pin to the resistive divider of the output. See Setting the Output Voltage section for more details.
EN	2	Enable Input. EN is a digital input that turns the regulator on or off. Drive EN high to turn on the regulator and low to turn it off. Connect to VIN or leave floating for automatic startup. The EN has a precision threshold of 1.18V for adjusting the UVLO. See Enable section for more details.
VIN	3	Power Input. VIN supplies the power to the IC as well as the step-down converter's power MOSFETs. Drive VIN with a 3.8V to 32V power source. Bypass VIN to GND with a suitably large capacitor to eliminate noise due to the switching of the IC. See Input Capacitor section for more details.
GND	4	Power Ground.
SW	5	Power Switching Output. SW is the switching node that supplies power to the output. Connect the output LC filter from SW to the output load.
BST	6	High-Side Gate Drive Boost Input. BST supplies the drive for the high-side N-channel power MOSFET. A 100nF capacitor is recommended from BST to SW to power the high-side driver.

Functional Block Diagram

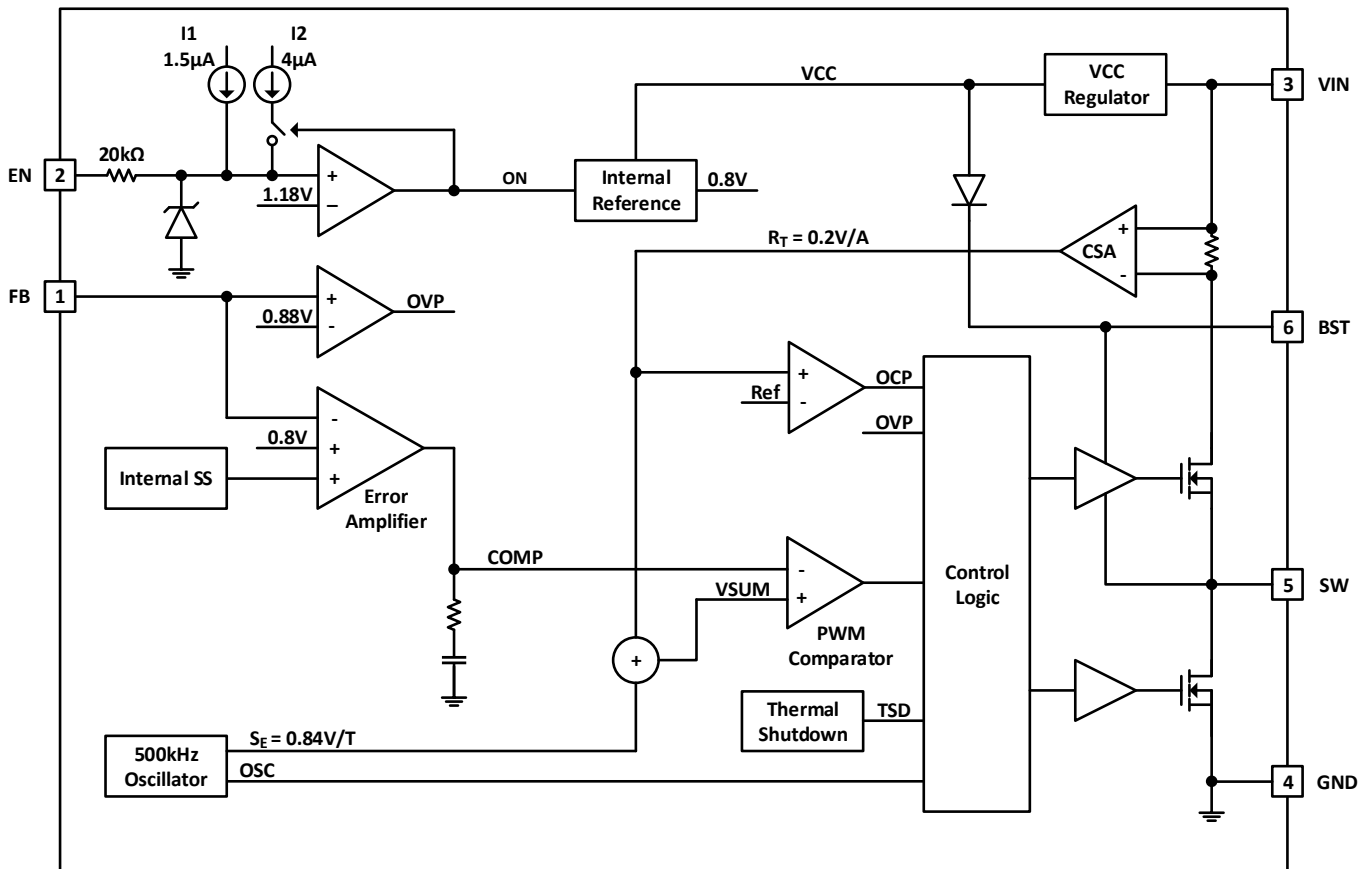

Figure 7. Functional Block Diagram

Absolute Maximum Ratings (Note 4) (@ T_A = +25°C, unless otherwise specified.)

Symbol	Parameter	Rating	Unit
VIN	Supply Pin Voltage	-0.3 to +35.0 (DC)	V
		-0.3 to +40.0 (400ms)	
V _{FB}	Feedback Pin Voltage	-0.3 to +6.0	V
V _{EN}	Enable/UVLO Pin Voltage	-0.3 to +35.0	V
V _{SW}	Switch Pin Voltage	-0.3 to VIN + 0.3 (DC)	V
		-2.5 to VIN + 2.0 (20ns)	
V _{BST}	Bootstrap Pin Voltage	V _{SW} - 0.3 to V _{SW} + 6.0	V
T _{STG}	Storage Temperature	-65 to +150	°C
T _J	Junction Temperature	+160	°C
T _L	Lead Temperature	+260	°C
ESD Susceptibility (Note 5)			
HBM	Human Body Model	±2000	V
CDM	Charged Device Model	±1500	V

- Notes:
- Stresses greater than the *Absolute Maximum Ratings* specified above can cause permanent damage to the device. These are stress ratings only; functional operation of the device at these or any other conditions exceeding those indicated in this specification is not implied. Device reliability can be affected by exposure to absolute maximum rating conditions for extended periods of time.
 - Semiconductor devices are ESD sensitive and can be damaged by exposure to ESD events. Suitable ESD precautions should be taken when handling and transporting these devices.

Thermal Resistance (Note 6)

Symbol	Parameter	Rating		Unit
		TSOT26		
θ _{JA}	Junction to Ambient	TSOT26	89	°C/W
θ _{JC}	Junction to Case	TSOT26	39	°C/W

- Note: 6. Test condition for TSOT26: Device mounted on FR-4 substrate, single-layer PC board, 2oz copper, with minimum recommended pad layout.

Recommended Operating Conditions (Note 7) (@ T_A = +25°C, unless otherwise specified.)

Symbol	Parameter	Min	Max	Unit
V _{IN}	Supply Voltage	3.8	32	V
V _{OUT}	Output Voltage	0.8	V _{IN}	V
T _A	Operating Ambient Temperature	-40	+125	°C
T _J	Operating Junction Temperature	-40	+150	°C

- Note: 7. The device function is not guaranteed outside of the recommended operating conditions.

Electrical Characteristics (@ $T_J = +25^\circ\text{C}$, $V_{IN} = 12\text{V}$, unless otherwise specified. Min/Max limits apply across the recommended operating junction temperature range, -40°C to $+150^\circ\text{C}$, and input voltage range, 3.8V to 32V, unless otherwise specified.)

Application Information

1 Pulse Width Modulation (PWM) Operation

The AP63200Q/AP63201Q/AP63203Q/AP63205Q device is an automotive-compliant, 3.8V-to-32V input, 2A output, EMI friendly, fully integrated synchronous buck converter. Refer to the block diagram in Figure 7. The device employs fixed-frequency peak current mode control. The internal clock's rising edge (500kHz for AP63200Q/AP63201Q, 1100kHz for AP63203Q/AP63205Q) initiates turning on the integrated high-side power MOSFET, Q1, for each cycle. When Q1 is on, the inductor current rises linearly and the device charges the output capacitor. The current across Q1 is sensed and converted to a voltage with a ratio of R_T via the CSA block. The CSA output is combined with an internal slope compensation, S_E , resulting in V_{SUM} . When V_{SUM} rises higher than the COMP node, the device turns off Q1 and turns on the low-side power MOSFET, Q2. The inductor current decreases when Q2 is on. On the rising edge of next clock cycle, Q2 turns off and Q1 turns on. This sequence repeats every clock cycle.

The error amplifier generates the COMP voltage by comparing the voltage on the FB pin with an internal 0.8V reference. An increase in load current causes the feedback voltage to drop. The error amplifier thus raises the COMP voltage until the average inductor current matches the increased load current. This feedback loop regulates the output voltage. The internal slope compensation circuitry prevents subharmonic oscillation when the duty cycle is greater than 50% for peak current mode control.

The peak current mode control, integrated loop compensation network, and built-in 4ms soft-start time simplifies the AP63200Q/AP63201Q/AP63203Q/AP63205Q footprint as well as minimizes the external component count.

In order to provide a small output ripple during light load conditions, the AP63201Q operates in PWM regardless of output load.

2 Pulse Frequency Modulation (PFM) Operation

In heavy load conditions, the AP63200Q/AP63203Q/AP63205Q operates in forced PWM mode. As the load current decreases, the internal COMP node voltage also decreases. At a certain limit, if the load current is low enough, the COMP node voltage is clamped and is prevented from decreasing any further. The voltage at which COMP is clamped corresponds to the 600mA PFM peak inductor current limit. As the load current approaches zero, the AP63200Q/AP63203Q/AP63205Q enters PFM mode to increase the converter power efficiency at light load conditions. When the inductor current decreases to 50mA, zero cross detection circuitry on the low-side power MOSFET, Q2, forces it off. The buck converter does not sink current from the output when the output load is light and while the device is in PFM. Because the AP63200Q/AP63203Q/AP63205Q works in PFM during light load conditions, it can achieve power efficiency of up to 88% at a 5mA load condition.

The quiescent current of AP63200Q/AP63203Q/AP63205Q is 22µA typical under a no-load, non-switching condition.

3 Enable

When disabled, the device shutdown supply current is only 1µA. When applying a voltage greater than the EN logic high threshold (typical 1.18V, rising), the AP63200Q/AP63201Q/AP63203Q/AP63205Q enables all functions and the device initiates the soft-start phase. The EN pin is a high-voltage pin and can be directly connected to VIN to automatically start up the device as VIN increases. An internal 1.5µA pull-up current source connected from the internal LDO-regulated VCC to the EN pin guarantees that if EN is left floating, the device still automatically enables once the voltage reaches the EN logic high threshold. The AP63200Q/AP63201Q/AP63203Q/AP63205Q has a built-in 4ms soft-start time to prevent output voltage overshoot and inrush current. When the EN voltage falls below its logic low threshold (typical 1.09V, falling), the internal SS voltage discharges to ground and device operation disables.

The EN pin can also be used to adjust the undervoltage lockout thresholds. See **Undervoltage Lockout (UVLO)** section for more details.

Alternatively, a small ceramic capacitor can be added from EN to GND. When EN is not driven externally, this capacitor increases the time needed for the EN pin voltage to reach its logic high threshold, which delays the startup of the output voltage. This is useful when sequencing multiple power rails to minimize input inrush current. When the EN pin voltage starts from 0V, the amount of capacitance for a given delay time is approximated by:

$$C_d[\text{nF}] \approx 1.27 \cdot t_d[\text{ms}] \tag{Eq. 1}$$

Where:

- C_d is the time delay capacitance in nF
- t_d is the delay time in ms

Application Information (continued)

4 Electromagnetic Interference (EMI) Reduction with Ringing-Free Switching Node and Frequency Spread Spectrum (FSS)

In some applications, the system must meet EMI standards. In relation to high frequency radiation EMI noise, the switching node's (SW's) ringing amplitude is especially critical. To dampen high frequency radiated EMI noise, the AP63200Q/AP63201Q/AP63203Q/AP63205Q device implements a proprietary, multi-level gate driver scheme that achieves a ringing-free switching node without sacrificing the switching node's rise and fall slew rates as well as the converter's power efficiency.

To further improve EMI reduction, the AP63200Q/AP63203Q/AP63205Q device also implements FSS with a switching frequency jitter of $\pm 6\%$. FSS reduces conducted and radiated interference at a particular frequency by spreading the switching noise over a wider frequency band and by not allowing emitted energy to stay in any one frequency for a significant period of time.

Additionally, the fixed output voltage devices, AP63203Q and AP63205Q, remove resonance ringing of the SW pin while in PFM mode when the inductor current is 0A. See Figure 73 for an example waveform.

Figure 73. AP63203Q/AP63205Q SW Pin Waveform

5 Adjusting Undervoltage Lockout (UVLO)

Undervoltage lockout is implemented to prevent the IC from insufficient input voltages. The AP63200Q/AP63201Q/AP63203Q/AP63205Q device has a UVLO comparator that monitors the input voltage and the internal bandgap reference. The AP63200Q/AP63201Q/AP63203Q/AP63205Q disables if the input voltage falls below 3.06V. In this UVLO event, both the high-side and low-side power MOSFETs turn off.

Some applications may desire higher VIN UVLO threshold voltages than is provided by the default setup. A 4µA hysteresis pull-up current source on the EN pin along with an external resistive divider (R3 and R4) configures the VIN UVLO threshold voltages as shown in Figure 74.

Figure 74. Adjusting UVLO

Application Information (continued)

5 Adjusting Undervoltage Lockout (UVLO) (continued)

The resistive divider resistor values are calculated by:

$$R3 = \frac{0.924 \cdot V_{ON} - V_{OFF}}{4.114\mu A} \quad \text{Eq. 2}$$

$$R4 = \frac{1.09 \cdot R3}{V_{OFF} - 1.09V + 5.5\mu A \cdot R3} \quad \text{Eq. 3}$$

Where:

- V_{ON} is the rising edge VIN voltage to enable the regulator and is greater than 3.7V
- V_{OFF} is the falling edge VIN voltage to disable the regulator and is greater than 3.26V

6 Output Overvoltage Protection (OVP)

The AP63200Q/AP63201Q/AP63203Q/AP63205Q implements output OVP circuitry to minimize output voltage overshoots during decreasing load transients. The high-side power MOSFET turns off, and the low-side power MOSFET turns on, when the feedback voltage exceeds 110% of the 0.8V internal reference voltage in order to prevent the output voltage from continuing to increase.

7 Overcurrent Protection (OCP)

The AP63200Q/AP63201Q/AP63203Q/AP63205Q has cycle-by-cycle peak current limit protection by sensing the current through the internal high-side power MOSFET, Q1. While Q1 is on, the internal sensing circuitry monitors its conduction current. Once the current through Q1 exceeds the peak current limit, Q1 immediately turns off. If Q1 consistently hits the peak current limit for 512 cycles, the buck converter enters hiccup mode and shuts down. After 8192 cycles of down time, the buck converter restarts powering up. Hiccup mode reduces the power dissipation in the overcurrent condition.

8 Thermal Shutdown (TSD)

If the junction temperature of the device reaches the thermal shutdown limit of +160°C, the AP63200Q/AP63201Q/AP63203Q/AP63205Q shuts down both its high-side and low-side power MOSFETs. When the junction temperature reduces to the required level (+135°C typical), the device initiates a normal power-up cycle with soft-start.

9 Power Derating Characteristics

To prevent the regulator from exceeding the maximum recommended operating junction temperature, some thermal analysis is required. The regulator's temperature rise is given by:

$$T_{RISE} = PD \cdot (\theta_{JA}) \quad \text{Eq. 4}$$

Where:

- PD is the power dissipated by the regulator
- θ_{JA} is the thermal resistance from the junction of the die to the ambient temperature

The junction temperature, T_J , is given by:

$$T_J = T_A + T_{RISE} \quad \text{Eq. 5}$$

Where:

- T_A is the ambient temperature of the environment

Application Information (continued)

9 Power Derating Characteristics (continued)

For the TSOT26 package, the θ_{JA} is 89°C/W. The actual junction temperature should not exceed the maximum recommended operating junction temperature of +150°C when considering the thermal design. Figure 75 and Figure 76 show typical derating curves versus ambient temperature.

Figure 75. Output Current Derating Curve vs. Ambient Temperature, AP63200Q/AP63201Q, VIN = 12V

Figure 76. Output Current Derating Curve vs. Ambient Temperature, AP63203Q/AP63205Q, VIN = 12V

10 Setting the Output Voltage

The AP63200Q/AP63201Q has adjustable output voltages starting from 0.8V using an external resistive divider. An optional external capacitor, C4 in Figure 1, of 10pF to 220pF improves the transient response. The resistor values of the feedback network are selected based on a design trade-off between efficiency and output voltage accuracy. There is less current consumption in the feedback network for high resistor values, which improves efficiency at light loads. However, values too high cause the device to be more susceptible to noise affecting its output voltage accuracy. R1 can be determined by the following equation:

$$R1 = R2 \cdot \left(\frac{VOUT}{0.8V} - 1 \right) \tag{Eq. 6}$$

Application Information (continued)

10 Setting the Output Voltage (continued)

Table 1 shows a list of recommended component selections for common AP63200Q/AP63201Q output voltages referencing Figure 1.

Table 1. Recommended Component Selections for AP63200Q/AP63201Q

AP63200Q/AP63201Q							
Output Voltage (V)	R1 (kΩ)	R2 (kΩ)	L (μH)	C1 (μF)	C2 (μF)	C3 (nF)	C4 (pF)
1.2	15.0	30.1	3.3	10	3 x 22	100	100
1.5	26.1	30.1	4.7	10	3 x 22	100	100
1.8	37.4	30.1	4.7	10	2 x 22	100	100
2.5	63.4	30.1	6.8	10	2 x 22	100	100
3.3	93.1	30.1	6.8	10	2 x 22	100	100
5.0	158.0	30.1	10.0	10	2 x 22	100	100
12.0	422.0	30.1	15.0	10	2 x 22	100	56

The AP63203Q/AP63205Q has a fixed output voltage. Table 2 and Table 3 show the recommended component selections for AP63203Q and AP63205Q referencing Figure 4.

Table 2. Recommended Component Selections for AP63203Q

AP63203Q				
Output Voltage (V)	L (μH)	C1 (μF)	C2 (μF)	C3 (nF)
3.3	3.3	10	2 x 22	100

Table 3. Recommended Component Selections for AP63205Q

AP63205Q				
Output Voltage (V)	L (μH)	C1 (μF)	C2 (μF)	C3 (nF)
5.0	4.7	10	2 x 22	100

11 Inductor

Calculating the inductor value is a critical factor in designing a buck converter. For most designs, the following equation can be used to calculate the inductor value:

$$L = \frac{V_{OUT} \cdot (V_{IN} - V_{OUT})}{V_{IN} \cdot \Delta I_L \cdot f_{SW}} \quad \text{Eq. 7}$$

Where:

- ΔI_L is the inductor current ripple
- f_{SW} is the buck converter switching frequency

For the AP63200Q/AP63201Q/AP63203Q/AP63205Q, choose ΔI_L to be 30% to 40% of the maximum load current of 2A.

The inductor peak current is calculated by:

$$I_{LPEAK} = I_{LOAD} + \frac{\Delta I_L}{2} \quad \text{Eq. 8}$$

Peak current determines the required saturation current rating, which influences the size of the inductor. Saturating the inductor decreases the converter efficiency while increasing the temperatures of the inductor and the internal power MOSFETs. Therefore, choosing an inductor with the appropriate saturation current rating is important. For most applications, it is recommended to select an inductor of approximately 3.3μH to 15μH with a DC current rating of at least 35% higher than the maximum load current. For highest efficiency, the inductor's DC resistance should be less than 30mΩ. Use a larger inductance for improved efficiency under light load conditions.

Application Information (continued)

12 Input Capacitor

The input capacitor reduces both the surge current drawn from the input supply as well as the switching noise from the device. The input capacitor must sustain the ripple current produced during the on-time of Q1. It must have a low ESR to minimize power dissipation due to the RMS input current.

The RMS current rating of the input capacitor is a critical parameter and must be higher than the RMS input current. As a rule of thumb, select an input capacitor with an RMS current rating greater than half of the maximum load current.

Due to large di/dt through the input capacitor, electrolytic or ceramic capacitors with low ESR should be used. If using a tantalum capacitor, it must be surge protected or else capacitor failure could occur. Using a ceramic capacitor of 10 μ F or greater is sufficient for most applications.

13 Output Capacitor

The output capacitor keeps the output voltage ripple small, ensures feedback loop stability, and reduces both the overshoots and undershoots of the output voltage during load transients. During the first few microseconds of an increasing load transient, the converter recognizes the change from steady-state and enters 100% duty cycle to supply more current to the load. However, the inductor limits the change to increasing current depending on its inductance. Therefore, the output capacitor supplies the difference in current to the load during this time. Likewise, during the first few microseconds of a decreasing load transient, the converter recognizes the change from steady-state and sets the on-time to minimum to reduce the current supplied to the load. However, the inductor limits the change in decreasing current as well. Therefore, the output capacitor absorbs the excess current from the inductor during this time.

The effective output capacitance, C_{OUT} , requirements can be calculated from the equations below.

The ESR of the output capacitor dominates the output voltage ripple. The amount of ripple can be calculated by:

$$V_{OUT_{Ripple}} = \Delta I_L \cdot \left(ESR + \frac{1}{8 \cdot f_{sw} \cdot C_{OUT}} \right) \quad \text{Eq. 9}$$

Output capacitors with large capacitance and low ESR are the best option. For most applications, a total capacitance of 2 x 22 μ F using ceramic capacitors is sufficient. To meet the load transient requirements, the calculated C_{OUT} should satisfy the following inequality:

$$C_{OUT} > \max \left(\frac{L \cdot I_{Trans}^2}{\Delta V_{Overshoot} \cdot V_{OUT}}, \frac{L \cdot I_{Trans}^2}{\Delta V_{Undershoot} \cdot (V_{IN} - V_{OUT})} \right) \quad \text{Eq. 10}$$

Where:

- I_{Trans} is the load transient
- $\Delta V_{Overshoot}$ is the maximum output overshoot voltage
- $\Delta V_{Undershoot}$ is the maximum output undershoot voltage

14 Bootstrap Capacitor and Low-Dropout (LDO) Operation

To ensure proper operation, a ceramic capacitor must be connected between the BST and SW pins to supply the drive voltage for the high-side power MOSFET. A 100nF ceramic capacitor is sufficient. If the bootstrap capacitor voltage falls below 2.3V, the boot undervoltage protection circuit turns Q2 on for 220ns to refresh the bootstrap capacitor and raise its voltage back above 2.85V. The bootstrap capacitor's voltage is always maintained to ensure enough driving capability for Q1. This operation may arise during long periods of no switching such as in PFM with light load conditions. Another event that requires the refreshing of the bootstrap capacitor is when the input voltage drops close to the output voltage. Under this condition, the regulator enters low-dropout mode by holding Q1 on for multiple clock cycles. To prevent the bootstrap capacitor from discharging, Q2 is forced to refresh. The effective duty cycle is approximately 100% so that it acts as an LDO to maintain the output voltage regulation.

Layout

PCB Layout

1. The AP63200Q/AP63201Q/AP63203Q/AP63205Q works at 2A load current so heat dissipation is a major concern in the layout of the PCB. 2oz copper for both the top and bottom layers is recommended.
2. Place the input capacitors as closely across VIN and GND as possible.
3. Place the inductor as close to SW as possible.
4. Place the output capacitors as close to GND as possible.
5. Place the feedback components as close to FB as possible, if applicable. If using AP63203Q/AP63205Q, tie the FB pin directly to VOUT as there is no need for R1, R2, or C4.
6. If using four or more layers, use at least the 2nd and 3rd layers as GND to maximize thermal performance.
7. Add as many vias as possible around both the GND pin and under the GND plane for heat dissipation to all the GND layers.
8. Add as many vias as possible around both the VIN pin and under the VIN plane for heat dissipation to all the VIN layers.
9. See Figure 77 for more details.
