

**HIGH RELIABILITY  
HYBRID DC/DC CONVERTERS**

**AHP28XXS SERIES**  
**28V Input, Single Output**

**Description**

The AHP Series of DC/DC converters feature high power density without derating over the full military temperature range. This series is offered as lower cost alternatives to the legendary AFL series with improved performance for new design applications. The AHPs are form, fit and functional replacement to the AFL series. The new AHP series offers a full compliment of single and dual output voltages operating from nominal +28 or +270 volt inputs with output power ranging from 66 to 120 watts. For applications requiring higher output power, multiple converters can be operated in parallel. The internal current sharing circuits assure equal current distribution among the paralleled converters. Same as the AFL, the AHP series incorporates International Rectifier's proprietary magnetic pulse feedback technology providing optimum dynamic line and load regulation response. This feedback system samples the output voltage at the pulse width modulator fixed clock frequency; nominally 550 KHz. Multiple converters can be synchronized to a system clock in the 500 KHz to 700 KHz range or to the synchronization output of one converter. Under-voltage lockout, primary and secondary referenced inhibit, soft-start and load fault protection are provided on all models. Also included is input over-voltage protection, a new protection feature unique to the AHP.

These converters are hermetically packaged in two enclosure variations, utilizing copper core pins to minimize resistive DC losses. Three lead styles are available, each fabricated with International Rectifier's rugged ceramic lead-to-package seal assuring long term hermeticity in harsh environments.

Manufactured in a facility fully qualified to MIL-PRF-38534, these converters are available in four screening grades to satisfy a wide range of requirements. The CH grade is fully compliant to the requirements of MIL-PRF-38534 for class H. The HB grade is fully processed and screened to the class H requirement, but does not have material element evaluated to the class H requirement. Both grades are tested to meet the

**Features**

- 16 To 40 Volt Input Range
- 3.3, 5, 8, 9,12,15 and 28 Volts Outputs Available
- High Power Density - up to 84 W / in<sup>3</sup>
- Up To 120 Watt Output Power
- Parallel Operation with Stress and Current Sharing
- Input Over-Voltage Protection
- High Efficiency - to 85%
- Continuous Short Circuit and Overload Protection
- External Synchronization Port
- Remote Sensing Terminals
- Primary and Secondary Referenced Inhibit Functions
- Line Rejection > 40 dB - DC to 50KHz
- Fault Tolerant Design
- Full Military Temperature Range
- Ceramic Feedthru Copper Core Pins
- Low Profile (0.380") Seam Welded Package
- Dual Output Versions Available

complete group "A" test specification over the full military temperature range without output power de-rating. Two grades with more limited screening are also available for use in less demanding applications. Variations in electrical, mechanical and screening can be accommodated. Please contact IR Santa Clara for special requirements.

### Notes to Specifications:

- Parameters not 100% tested but are guaranteed to the limits specified in the table.
- Recovery time is measured from the initiation of the transient to where  $V_{\text{OUT}}$  has returned to within  $\pm 1\%$  of  $V_{\text{OUT}}$  at 50% load.
- Line transient transition time  $\geq 100 \mu\text{s}$ .
- Turn-on delay is measured with an input voltage rise time of between 100 and 500 volts per millisecond.
- Current limit point is that condition of excess load causing output voltage to drop to 90% of nominal.
- Parameter verified as part of another test.
- All electrical tests are performed with the remote sense leads connected to the output leads at the load.
- Load transient transition time  $\geq 10 \mu\text{s}$ .
- Enable inputs internally pulled high. Nominal open circuit voltage  $\approx 4.0\text{VDC}$ .

**AHP28XXS Circuit Description**

Figure I. AHP Single Output Block Diagram

**Circuit Operation and Application Information**

The AHP series of converters employ a forward switched mode converter topology. (refer to Figure I.) Operation of the device is initiated when a DC voltage whose magnitude is within the specified input limits is applied between pins 1 and 2. If pin 4 is enabled (at a logical 1 or open) the primary bias supply will begin generating a regulated housekeeping voltage bringing the circuitry on the primary side of the converter to life. A power MOSFET is used to chop the DC input voltage into a high frequency square wave, applying this chopped voltage to the power transformer at the nominal converter switching frequency. Maintaining a DC voltage within the specified operating range at the input assures continuous generation of the primary bias voltage.

The switched voltage impressed on the secondary output transformer winding is rectified and filtered to generate the converter DC output voltage. An error amplifier on the secondary side compares the output voltage to a precision reference and generates an error signal proportional to the difference. This error signal is magnetically coupled through the feedback transformer into the controller section of the converter varying the pulse width of the square wave signal driving the MOSFET, narrowing the width if the output voltage is too high and widening it if it is too low, thereby regulating the output voltage.

**Remote Sensing**

Connection of the + and - sense leads at a remotely located load permits compensation for excessive resistance between the converter output and the load when their physical separation could cause undesirable voltage drop. This connection allows regulation to the placard voltage at the point of application. When the remote sensing feature is not used the sense leads should be connected to their respective output terminals at the converter. Figure III. illustrates a typical remotely sensed application.

**Inhibiting Converter Output**

As an alternative to application and removal of the DC voltage to the input, the user can control the converter output by providing TTL compatible, positive logic signals to either of two enable pins (pin 4 or 12). The distinction between these two signal ports is that enable 1 (pin 4) is referenced to the input return (pin 2) while enable 2 (pin 12) is referenced to the output return (pin 8). Thus, the user has access to an inhibit function on either side of the isolation barrier. Each port is internally pulled "high" so that when not used, an open connection on both enable pins permits normal converter operation. When their use is desired, a logical "low" on either port will shut the converter down.

Figure II. Enable Input Equivalent Circuit

Internally, these ports differ slightly in their function. In use, a low on Enable 1 completely shuts down all circuits in the converter, while a low on Enable 2 shuts down the secondary side while altering the controller duty cycle to near zero. Externally, the use of either port is transparent save for minor differences in standby current. (See specification table).

**Synchronization of Multiple Converters**

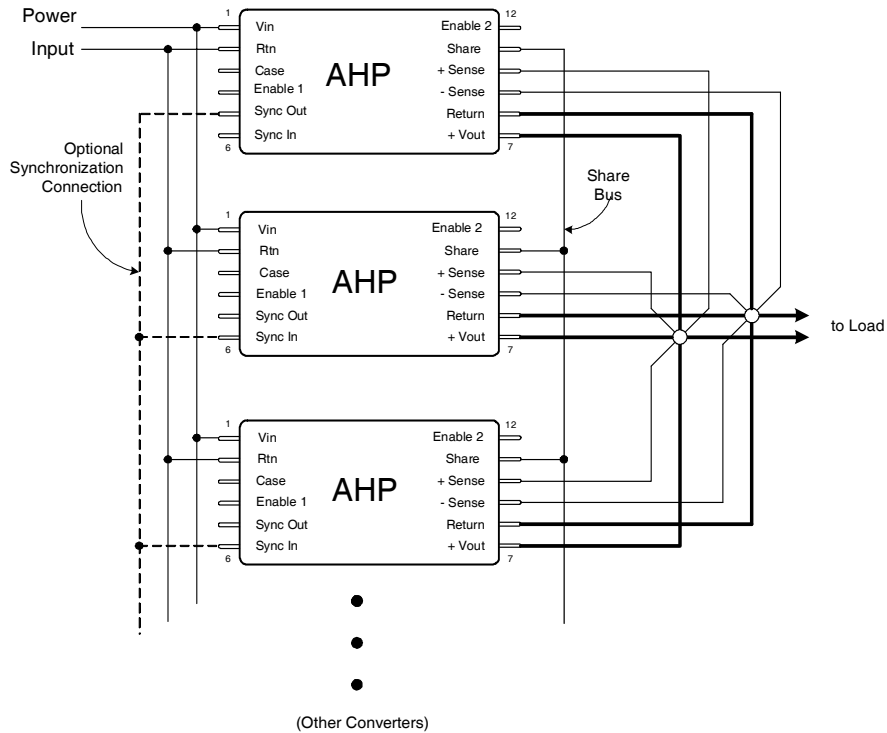

When operating multiple converters, system requirements often dictate operation of the converters at a common frequency. To accommodate this requirement, the AHP series converters provide both a synchronization input and a synchronization output.

The sync input port permits synchronization of an AHP converter to any compatible external frequency source operating between 500 and 700 KHz. This input signal should be referenced to the input return and have a 10% to 90% duty cycle. Compatibility requires transition times less than 100 ns, maximum low level of +0.8 volts and a minimum high level of +2.0 volts. The sync output of another converter which has been designated as the master oscillator provides a convenient frequency source for this mode of operation.

When external synchronization is not required, the sync in pin should be left open (unconnected) thereby permitting the converter to operate at its' own internally set frequency.

The sync output signal is a continuous pulse train set at  $550 \pm 50$  KHz, with a duty cycle of  $15 \pm 5\%$ . This signal is referenced to the input return and has been tailored to be compatible with the AHP sync input port. Transition times are less than 100 ns and the low level output impedance is less than 50 ohms. This signal is active when the DC input voltage is within the specified operating range and the converter is not inhibited. This output has adequate drive reserve to synchronize at least five additional converters. A typical connection is illustrated in Figure III.

Figure III. Preferred Connection for Parallel Operation

**Parallel Operation-Current and Stress Sharing**

Figure III. illustrates the preferred connection scheme for operation of a set of AHP converters with outputs operating in parallel. Use of this connection permits equal sharing among the members of a set whose load current exceeds the capacity of an individual AHP. An important feature of

AHP series operating in the parallel mode is that in addition to sharing the current, the stress induced by temperature will also be shared. Thus if one member of a paralleled set is operating at a higher case temperature, the current it provides to the load will be reduced as compensation for the temperature induced stress on that device.

When operating in the shared mode, it is important that symmetry of connection be maintained as an assurance of optimum load sharing performance. Thus, converter outputs should be connected to the load with equal lengths of wire of the same gauge and should be connected to a common physical point, preferably at the load along with the converter output and return leads. All converters in a paralleled set must have their share pins connected together. This arrangement is diagrammatically illustrated in Figure III, showing the output and return pins connected at a star point which is located as close as possible to the load.

As a consequence of the topology utilized in the current sharing circuit, the share pin may be used for other functions. In applications requiring only a single converter, the voltage appearing on the share pin may be used as a "current monitor". The share pin open circuit voltage is nominally +1.00v at no load and increases linearly with increasing total output current to +2.20v at full load.

### Thermal Considerations

Because of the incorporation of many innovative technological concepts, the AHP series of converters is capable of providing very high output power from a package of very small volume. These magnitudes of power density can only be obtained by combining high circuit efficiency with effective methods of heat removal from the die junctions. This requirement has been effectively addressed inside the device; but when operating at maximum loads, a significant amount of heat will be generated and this heat must be conducted away from the case. To maintain the case temperature at or below the specified maximum of 125°C, this heat must be transferred by conduction to an appropriate heat dissipater held in intimate contact with the converter base-plate.

Because the effectiveness of this heat transfer is dependent on the intimacy of the baseplate/heatsink interface, it is strongly recommended that a high thermal conductivity heat transferring medium is inserted between the baseplate and heatsink. The material most frequently utilized at the factory during all testing and burn-in processes is sold under the trade name of Sil-Pad® 400<sup>1</sup>. This particular product is an insulator but electrically conductive versions are also available. Use of these materials assures maximum surface contact with the heat dissipater thereby compensating for any minor surface variations. While other available types of heat conductive materials and thermal compounds provide similar effectiveness, these alternatives are often less convenient and can be somewhat messy to use.

<sup>1</sup>Sil-Pad is a registered Trade Mark of Bergquist, Minneapolis, MN

A conservative aid to estimating the total heat sink surface area ( $A_{\text{HEAT SINK}}$ ) required to set the maximum case temperature rise ( $\Delta T$ ) above ambient temperature is given by the following expression:

$$A_{\text{HEAT SINK}} \approx \left\{ \frac{\Delta T}{80P^{0.85}} \right\}^{-1.43} - 3.0$$

where

$\Delta T$  = Case temperature rise above ambient

$$P = \text{Device dissipation in Watts} = P_{\text{OUT}} \left\{ \frac{1}{\text{Eff}} - 1 \right\}$$

As an example, it is desired to maintain the case temperature of an AHP2815S at  $\leq +85^\circ\text{C}$  while operating in an open area whose ambient temperature is held at a constant  $+25^\circ\text{C}$ ; then

$$\Delta T = 85 - 25 = 60^\circ\text{C}$$

From the Specification Table, the worst case full load efficiency for this device is 83%; therefore the power dissipation at full load is given by

$$P = 120 \cdot \left\{ \frac{1}{.83} - 1 \right\} = 120 \cdot (0.205) = 24.6\text{W}$$

and the required heat sink area is

$$A_{\text{HEAT SINK}} = \left\{ \frac{60}{80 \cdot 24.6^{0.85}} \right\}^{-1.43} - 3.0 = 71 \text{ in}^2$$

Thus, a total heat sink surface area (including fins, if any) of 71 in<sup>2</sup> in this example, would limit case rise to 60°C above ambient. A flat aluminum plate, 0.25" thick and of approximate dimension 4" by 9" (36 in<sup>2</sup> per side) would suffice for this application in a still air environment. Note that to meet the criteria in this example, both sides of the plate require unrestricted exposure to the ambient air.

## AHP28XXS Series

International  
IR Rectifier

### Input Filter

The AHP28XXS series converters incorporate a single stage LC input filter whose elements dominate the input load impedance characteristic during the turn-on. The input circuit is as shown in Figure IV.

### Input Over-Voltage Protection

One additional protection feature is incorporated into the AHP input circuit. It is an input over-voltage protection. The output will shutdown and restart at approximately 110% of the maximum rated input voltage. This protection feature is unique to the AHP.

### Undervoltage Lockout

A minimum voltage is required at the input of the converter to initiate operation. This voltage is set to  $14.0 \pm 0.5$  volts. To preclude the possibility of noise or other variations at the input falsely initiating and halting converter operation, a hysteresis of approximately 1.0 volts is incorporated in this circuit. Thus if the input voltage droops to  $13.0 \pm 0.5$  volts, the converter will shut down and remain inoperative until the input voltage returns to  $\approx 14.0$  volts.

### Output Voltage Adjust

In addition to permitting close voltage regulation of remotely located loads, it is possible to utilize the converter sense pins to incrementally increase the output voltage over a limited range. The adjustments made possible by this method are intended as a means to "trim" the output to a voltage setting for some particular application, but are not intended to create an adjustable output converter. These output voltage setting variations are obtained by connecting an appropriate resistor value in the locations as shown in Figure V or Figure VI depending on the desired output voltage. The range of adjustment and corresponding range of resistance values can be determined by use of the equations presented below.

For  $(V_{NOM} + 0.25V) < V_{OUT} < (V_{NOM} + 0.5V)$ , a resistor is connected between the +Sense and -Sense pins with the -Sense connected to the output return as shown in Figure V. The resistor value ( $R_{ADJ}$ ) is calculated as follows:

$$R_{ADJ} = 1000 \cdot \left[ \frac{V_{NOM}}{V_{OUT} - V_{NOM} - 0.25} \right]$$

For  $V_{NOM} < V_{OUT} < (V_{NOM} + 0.25V)$ , a resistor is connected between the +Sense and +Output pins with the -Sense connected to the output return as shown in Figure VI. The resistor value ( $R_{ADJ}$ ) is calculated as follows:

$$R_{ADJ} = \frac{1000}{\left( \frac{0.25}{V_{OUT} - V_{NOM}} - 1 \right)}$$

$V_{NOM}$  = device nominal output voltage

$V_{OUT}$  = desired output voltage

$R_{ADJ}$  = value of the external resistor required to achieve the desired  $V_{out}$

Finding a resistor value for a particular output voltage, is simply a matter of substituting the desired output voltage and the nominal device voltage into the equation and solving for the corresponding resistor value.

Figure V. Connection for  $V_{OUT} > V_{NOM} + 0.25V$

Figure VI. Connection for  $V_{NOM} < V_{OUT} < (V_{NOM} + 0.25V)$

Attempts to adjust the output voltage to a value greater than 120% of nominal should be avoided because of the potential of exceeding internal component stress ratings and subsequent operation to failure. Under no circumstance should the external setting resistor be made less than 500Ω. By remaining within this specified range of values, completely safe operation fully within normal component derating is assured.

Examination of the equation relating output voltage and resistor value reveals a special benefit of the circuit topology utilized for remote sensing of output voltage in the AHP28XXS series of converters. It is apparent that as the resistance increases, the output voltage approaches the nominal set value of the device. In fact the calculated limiting value of output voltage as the adjusting resistor becomes very large is  $\cong 250\text{mV}$  above nominal device voltage.

The consequence is that if the +sense connection is unintentionally broken, an AHP28XXS has a fail-safe output voltage of  $V_{out} + 250\text{mV}$ , where the 250mV is independent of the nominal output voltage. It can be further demonstrated that in the event of both the + and - sense connections being broken, the output will be limited to  $V_{out} + 500\text{mV}$ . This 500mV is also essentially constant independent of the nominal output voltage. While operation in this condition is not damaging to the device, not all performance parameters will be met.

### General Application Information

The AHP28XXS series of converters are capable of providing large transient currents to user loads on demand. Because the nominal input voltage range in this series is relatively low, the resulting input current demands will be correspondingly large. It is important therefore, that the line impedance be kept very low to prevent steady state and transient input currents from degrading the supply voltage between the voltage source and the converter input.

In applications requiring high static currents and large transients, it is recommended that the input leads be made of adequate size to minimize resistive losses, and that a good quality capacitor of approximately 100μfd be connected directly across the input terminals to assure an adequately low impedance at the input terminals. Table I relates nominal resistance values and selected wire sizes.

Table 1. Nominal Resistance of Cu Wire

Wire Size, AWG	Resistance per ft
24 Ga	25.7 mΩ
22 Ga	16.2 mΩ
20 Ga	10.1 mΩ
18 Ga	6.4 mΩ
16 Ga	4.0 mΩ
14 Ga	2.5 mΩ
12 Ga	1.6 mΩ

As an example of the effects of parasitic resistance, consider an AHP2815S operating at full power of 120 W. From the specification sheet, this device has a minimum efficiency of 83% which represents an input power of more than 145 W. If we consider the case where line voltage is at its minimum of 16 volts, the steady state input current necessary for this example will be slightly greater than 9 amperes. If this device were connected to a voltage source with 10 feet of 20 gauge wire, the round trip (input and return) would result in 0.2 Ω of resistance and 1.8 volts of drop from the source to the converter. To assure 16 volts at the input, a source closer to 18 volts would be required. In applications using the paralleling option, this drop will be multiplied by the number of paralleled devices.

By choosing 14 or 16 gauge wire in this example, the parasitic resistance and resulting voltage drop will be reduced to 25% or 31% of that with 20 gauge wire.

Another potential problem resulting from parasitically induced voltage drop on the input lines is with regard to the operation of the enable 1 port. The minimum and maximum operating levels required to operate this port are specified with respect to the input common return line at the converter. If a logic signal is generated with respect to a 'common' that is distant from the converter, the effects of the voltage drop over the return line must be considered when establishing the worst case TTL switching levels. These drops will effectively impart a shift to the logic levels. In Figure VII, it can be seen that referred to system ground, the voltage on the input return pin is given by

$$e_{Rin} = I_{Rin} \cdot R_p$$

## AHP28XXS Series

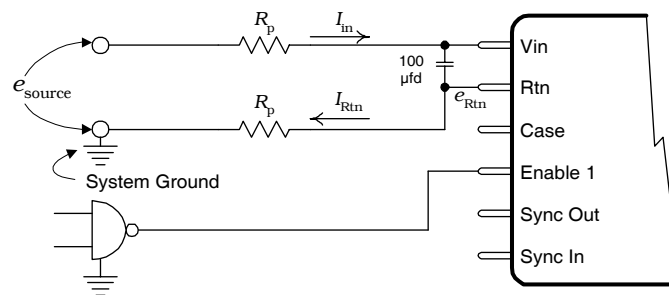

International  
**IR** Rectifier

Therefore, the logic signal level generated in the system must be capable of a TTL logic high plus sufficient additional amplitude to overcome  $e_{R_{tn}}$ . When the converter is inhibited,  $I_{R_{tn}}$  diminishes to near zero and  $e_{R_{tn}}$  will then be at system ground.

Incorporation of a 100  $\mu\text{fd}$  capacitor at the input terminals is recommended as compensation for the dynamic effects of the parasitic resistance of the input cable reacting with the complex impedance of the converter input, and to provide an energy reservoir for transient input current requirements.

Figure VII. Problems of Parasitic Resistance in input Leads

**BERYLLIA WARNING:** These converters are hermetically sealed; however they contain BeO substrates and should not be ground or subjected to any other operations including exposure to acids, which may produce Beryllium dust or fumes containing Beryllium

**Available Screening Levels and Process Variations for AHP28XXS Series.**

Requirement	MIL-STD-883 Method	No Suffix	ES Suffix	HB Suffix	CH Suffix
Temperature Range		-20°C to +85°C	-55°C to +125°C	-55°C to +125°C	-55°C to +125°C
Element Evaluation					MIL-H-38534
Internal Visual	2017	*	✓	✓	✓
Temperature Cycle	1010		Cond B	Cond C	Cond C
Constant Acceleration	2001, Y1 Axis		500g	3000g	3000g
Burn-in	1015	48hrs @ 85°C	48hrs @ 125°C	160hrs @ 125°C	160hrs @ 125°C
Final Electrical (Group A)	MIL-PRF-38534 Specification	25°C	25°C	-55, +25, +125°C	-55, +25, +125°C
Seal, Fine & Gross	1014	Cond C	Cond A, C	Cond A, C	Cond A, C
External Visual	2009	*	✓	✓	✓

\* per Commercial Standards

**AHP28XXS Pin Designation**

Pin No.	Designation
1	Positive Input
2	Input Return
3	Case
4	Enable 1
5	Sync Output
6	Sync Input
7	Positive Output
8	Output Return
9	Return Sense
10	Positive Sense
11	Share
12	Enable 2

**Part Numbering**

**AHP 28 05 S X / CH**
