SERIAL FLASH MEMORY WITH 166MHZ MULTI I/O SPI & QUAD I/O QPI DTR INTERFACE

PRELIMINARY INFORMATION

FEATURES

- **Industry Standard Serial Interface**
 - IS25LP064D: 64Mbit/8Mbyte
 - IS25WP064D: 64Mbit/8Mbyte
 - Supports Standard SPI, Fast, Dual, Dual I/O, Quad, Quad I/O, SPI DTR, Dual I/O DTR, Quad I/O DTR, and QPI
 - Software & Hardware Reset
 - Supports Serial Flash Discoverable Parameters (SFDP)
- **High Performance Serial Flash (SPI)**
 - 80MHz Normal Read
 - Up to 166MHz Fast Read
 - Up to 80MHz DTR (Dual Transfer Rate)
 - Equivalent Throughput of 664 Mb/s
 - Selectable Dummy Cycles
 - Configurable Drive Strength
 - Supports SPI Modes 0 and 3
 - More than 100,000 Erase/Program Cycles
 - More than 20-year Data Retention
- **Flexible & Efficient Memory Architecture**
 - Chip Erase with Uniform Sector/Block Erase (4/32/64 Kbyte)
 - Program 1 to 256 Byte per Page
 - Program/Erase Suspend & Resume
- **Efficient Read and Program modes**
 - Low Instruction Overhead Operations
 - Continuous Read 8/16/32/64 Byte Burst Wrap
 - Selectable Burst Length
 - QPI for Reduced Instruction Overhead
 - AutoBoot Operation
- **Low Power with Wide Temp. Ranges**
 - Single Voltage Supply
 - IS25LP: 2.30V to 3.60V
 - IS25WP: 1.65V to 1.95V ⁽¹⁾
 - 10 mA Active Read Current
 - 8 μ A Standby Current
 - 1 μ A Deep Power Down
 - Temp Grades:
 - Extended: -40°C to +105°C
 - Auto Grade (A3) : -40°C to +125°C
- **Advanced Security Protection**
 - Software and Hardware Write Protection
 - Advanced Sector/Block Protection
 - Top/Bottom Block Protection
 - Power Supply Lock Protection
 - 4x256 Byte Dedicated Security Area with OTP User-lockable Bits
 - 128 bit Unique ID for Each Device (Call Factory)
- **Industry Standard Pin-out & Packages⁽²⁾**
 - M = 16-pin SOIC 300mil
 - B = 8-pin SOIC 208mil
 - K = 8-contact WSON 6x5mm
 - L = 8-contact WSON 8x6mm
 - G = 24-ball TFBGA (4x6 ball array)
 - H = 24-ball TFBGA (5x5 ball array)
 - KGD (Call Factory)

Notes:

1. Call Factory for 1.8V (IS25WP064D) device.
2. Call Factory for other package options available.

GENERAL DESCRIPTION

The IS25LP064D and IS25WP064D Serial Flash memory offers a versatile storage solution with high flexibility and performance in a simplified pin count package. ISSI's "Industry Standard Serial Interface" Flash is for systems that require limited space, a low pin count, and low power consumption. The device is accessed through a 4-wire SPI Interface consisting of a Serial Data Input (SI), Serial Data Output (SO), Serial Clock (SCK), and Chip Enable (CE#) pins, which can also be configured to serve as multi-I/O (see pin descriptions).

The device supports Dual and Quad I/O as well as standard, Dual Output, and Quad Output SPI. Clock frequencies of up to 166MHz allow for equivalent clock rates of up to 664MHz (166MHz x 4) which equates to 83Mbytes/s of data throughput. The IS25xP series of Flash adds support for DTR (Double Transfer Rate) commands that transfer addresses and read data on both edges of the clock. These transfer rates can outperform 16-bit Parallel Flash memories allowing for efficient memory access to support XIP (execute in place) operation.

Initial state of the memory array is erased (all bits are set to 1) when shipped from the factory.

QPI (Quad Peripheral Interface) supports 2-cycle instruction further reducing instruction times. Pages can be erased in groups of 4Kbyte sectors, 32Kbyte blocks, 64Kbyte blocks, and/or the entire chip. The uniform sector and block architecture allows for a high degree of flexibility so that the device can be utilized for a broad variety of applications requiring solid data retention.

Supply Voltage & Temperature Range vs. Maximum Speed

	Voltage & Temp.	Speed
IS25LP (3.0V typ.)	2.30~3.6V, 125°C	133MHz
	2.70~3.6V, 125°C	166MHz
IS25WP (1.8V typ.) ⁽²⁾	1.65~1.95V, 125°C	133MHz
	1.70~1.95V, 105°C	166MHz ⁽¹⁾

Note:

1. Values are guaranteed by characterization and not 100% tested in production.
2. Call Factory for 1.8V device

1. PIN CONFIGURATION

8-pin SOIC 208mil

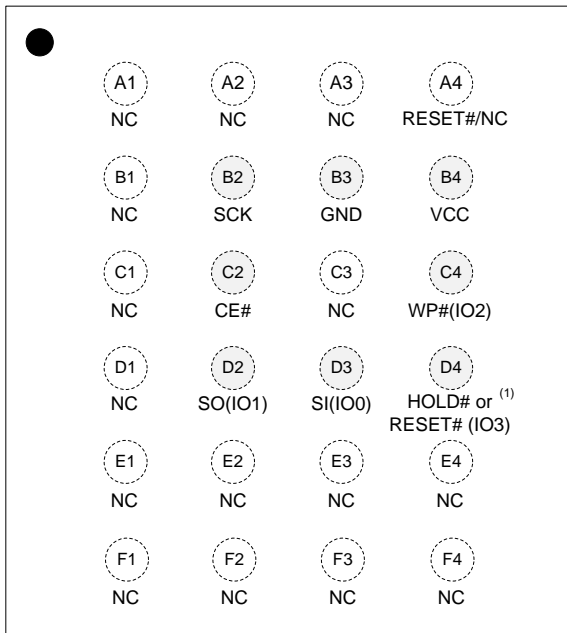

8-contact WSON 6x5mm
8-contact WSON 8x6mm

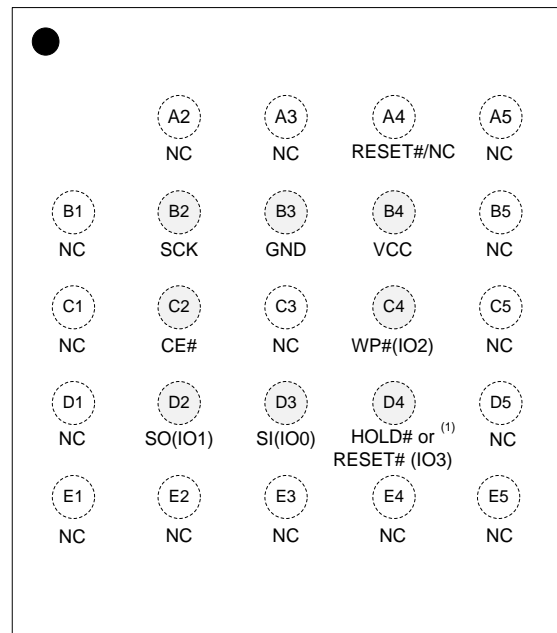

16-pin SOIC 300mil (Package: M)

Top View, Balls Facing Down

24-ball TFBGA 6x8mm (4x6 ball array)
(Package: G)

Top View, Balls Facing Down

24-ball TFBGA 6x8mm (5x5 ball array)
(Package: H)

Note:

1. The pin can be configured as Hold# or Reset# by setting P7 bit of the Read Register. Pin default is Hold# (IO3).

2. PIN DESCRIPTIONS

SYMBOL	TYPE	DESCRIPTION
CE#	INPUT	<p>Chip Enable: The Chip Enable (CE#) pin enables and disables the devices operation. When CE# is high the device is deselected and output pins are in a high impedance state. When deselected the devices non-critical internal circuitry power down to allow minimal levels of power consumption while in a standby state.</p> <p>When CE# is pulled low the device will be selected and brought out of standby mode. The device is considered active and instructions can be written to, data read, and written to the device. After power-up, CE# must transition from high to low before a new instruction will be accepted.</p> <p>Keeping CE# in a high state deselects the device and switches it into its low power state. Data will not be accepted when CE# is high.</p>
SI (IO0), SO (IO1)	INPUT/OUTPUT	<p>Serial Data Input, Serial Output, and IOs (SI, SO, IO0, and IO1):</p> <p>This device supports standard SPI, Dual SPI, and Quad SPI operation. Standard SPI instructions use the unidirectional SI (Serial Input) pin to write instructions, addresses, or data to the device on the rising edge of the Serial Clock (SCK). Standard SPI also uses the unidirectional SO (Serial Output) to read data or status from the device on the falling edge of the serial clock (SCK).</p> <p>In Dual and Quad SPI mode, SI and SO become bidirectional IO pins to write instructions, addresses or data to the device on the rising edge of the Serial Clock (SCK) and read data or status from the device on the falling edge of SCK. Quad SPI instructions use the WP# and HOLD# pins as IO2 and IO3 respectively.</p>
WP# (IO2)	INPUT/OUTPUT	<p>Write Protect/Serial Data IO (IO2): The WP# pin protects the Status Register from being written in conjunction with the SRWD bit. When the SRWD is set to "1" and the WP# is pulled low, the Status Register bits (SRWD, QE, BP3, BP2, BP1, BP0) are write-protected and vice-versa for WP# high. When the SRWD is set to "0", the Status Register is not write-protected regardless of WP# state.</p> <p>When the QE bit is set to "1", the WP# pin (Write Protect) function is not available since this pin is used for IO2.</p>
HOLD# (IO3) or RESET# (IO3)	INPUT/OUTPUT	<p>HOLD# or RESET#/Serial Data IO (IO3): When the QE bit of Status Register is set to "1", HOLD# pin or RESET# is not available since it becomes IO3.</p> <p>Most packages except for 16-pin SOIC and 24-ball BGA:</p> <p>When QE=0, the pin acts as HOLD# or RESET# and either one can be selected by the P7 bit setting in Read Register. HOLD# will be selected if P7=0 (Default) and RESET# will be selected if P7=1.</p> <p>16-pin SOIC and 24-ball BGA packages :</p> <ul style="list-style-type: none"> - When QE=0 and Dedicated RESET# is Enabled (Default), the pin acts as HOLD# regardless of the P7 bit setting in Read Register. - When QE=0 and Dedicated RESET# is Disabled, the pin acts as HOLD# or RESET# and either one can be selected by the P7 bit setting in Read Register. HOLD# will be selected if P7=0 (Default) and RESET# will be selected if P7=1. <p>The HOLD# pin allows the device to be paused while it is selected. It pauses serial communication by the master device without resetting the serial sequence. The HOLD# pin is active low. When HOLD# is in a low state and CE# is low, the SO pin will be at high impedance. Device operation can resume when HOLD# pin is brought to a high state.</p>

SYMBOL	TYPE	DESCRIPTION
RESET#	INPUT	<p>RESET#: This dedicated RESET# is available in 16-pin SOIC and 24-ball BGA packages.</p> <p>The RESET# pin is a hardware RESET signal. When RESET# is driven HIGH, the memory is in the normal operating mode. When RESET# is driven LOW, the memory enters reset mode and output is High-Z. If RESET# is driven LOW while an internal WRITE, PROGRAM, or ERASE operation is in progress, data may be lost.</p> <p>Dedicated RESET# function can be Disabled when bit 0 of Function Register = 1. It has an internal pull-up resistor and may be left floating if not used.</p>
SCK	INPUT	Serial Data Clock: Synchronized Clock for input and output timing operations.
Vcc	POWER	Power: Device Core Power Supply
GND	GROUND	Ground: Connect to ground when referenced to Vcc
NC	Unused	NC: Pins labeled "NC" stand for "No Connect" and should be left uncommitted.

3. BLOCK DIAGRAM

Note:

1: In case of 16-pin SOIC or 24-ball TFBFA, when QE=0 and Dedicated RESET# is Disabled, the pin acts as HOLD# or RESET# and either one can be selected by the P7 bit setting in Read Register. HOLD# will be selected if P7=0 (Default) and RESET# will be selected if P7=1.

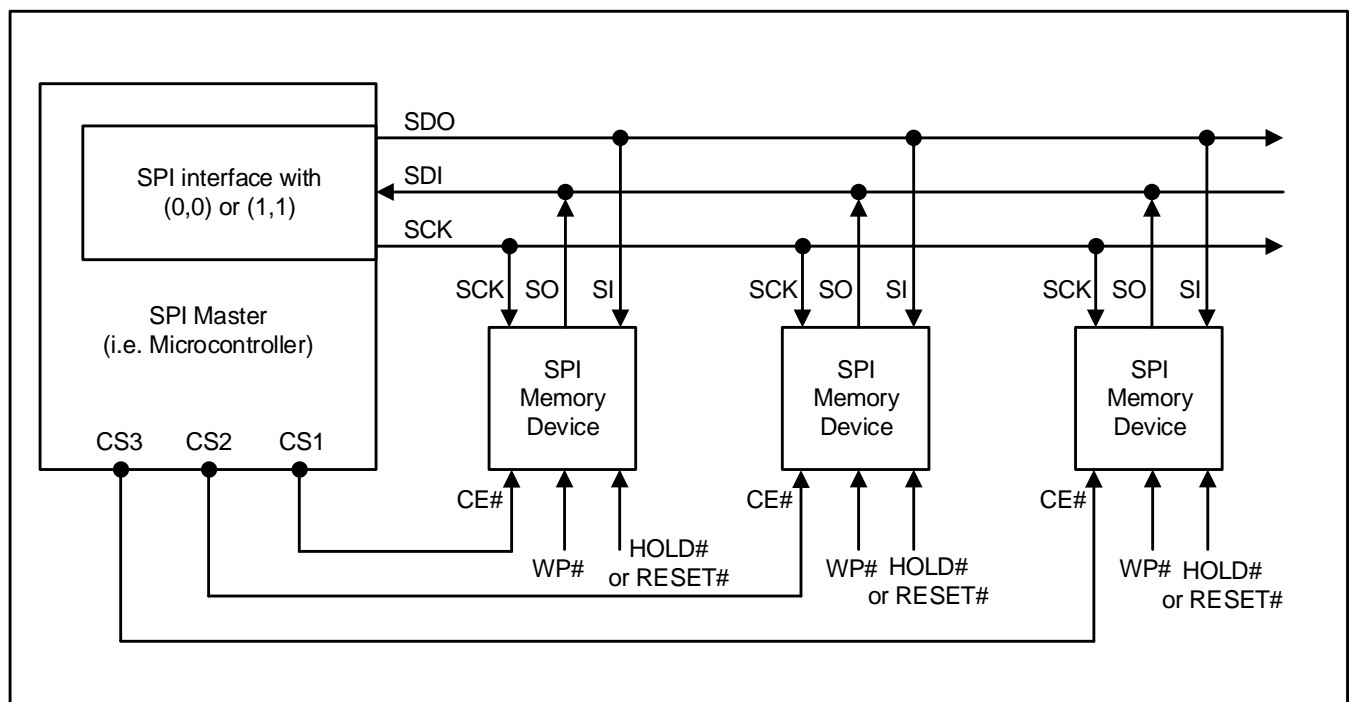

4. SPI MODES DESCRIPTION

Multiple IS25LP064D devices or multiple IS25WP064D devices can be connected on the SPI serial bus and controlled by a SPI Master, i.e. microcontroller, as shown in Figure 4.1. The devices support either of two SPI modes:

- Mode 0 (0, 0)
- Mode 3 (1, 1)

The difference between these two modes is the clock polarity. When the SPI master is in stand-by mode, the serial clock remains at “0” (SCK = 0) for Mode 0 and the clock remains at “1” (SCK = 1) for Mode 3. Please refer to Figure 4.2 and Figure 4.3 for SPI and QPI mode. In both modes, the input data is latched on the rising edge of Serial Clock (SCK), and the output data is available from the falling edge of SCK.

Figure 4.1 Connection Diagram among SPI Master and SPI Slaves (Memory Devices)

Notes:

1. In case of 16-pin SOIC and 24-ball TFBGA, dedicated RESET# is supported.
2. SI and SO pins become bidirectional IO0 and IO1 respectively during Dual I/O mode and SI, SO, WP#, and HOLD# pins become bidirectional IO0, IO1, IO2, and IO3 respectively during Quad I/O or QPI mode.

Figure 4.2 SPI Mode Support

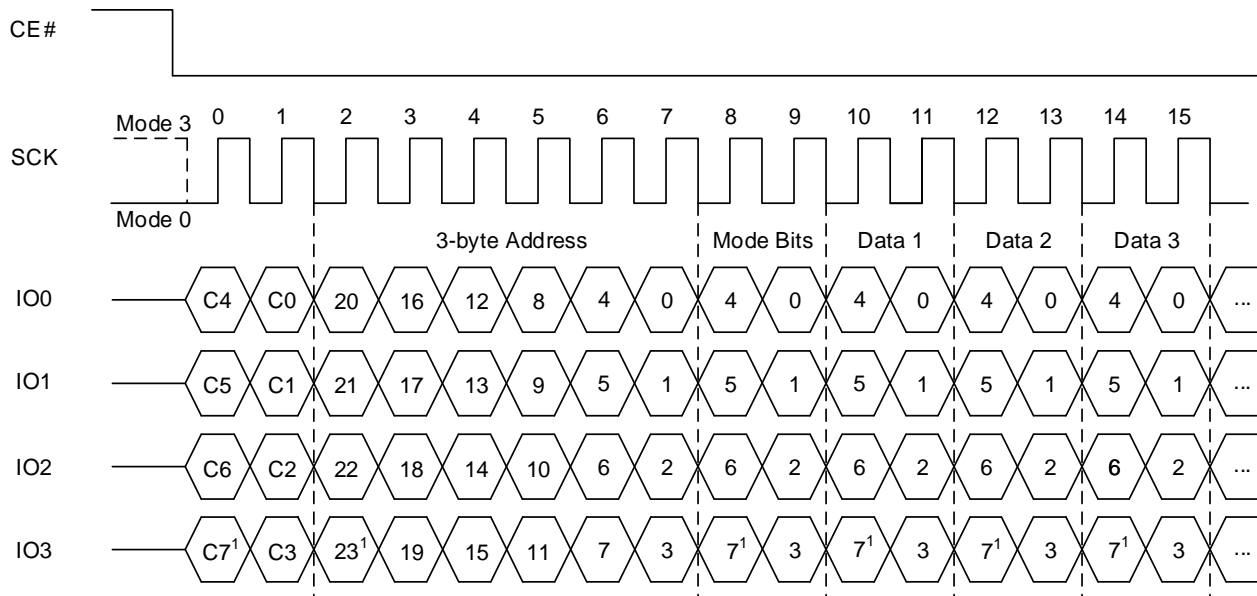

Figure 4.3 QPI Mode Support

Note1: MSB (Most Significant Bit)

5. SYSTEM CONFIGURATION

The memory array is divided into uniform 4 Kbyte sectors or uniform 32/64 Kbyte blocks (a block consists of eight/sixteen adjacent sectors respectively).

Table 5.1 illustrates the memory map of the device. The Status Register controls how the memory is protected.

5.1 BLOCK/SECTOR ADDRESSES

Table 5.1 Block/Sector Addresses

Memory Density	Block No. (64Kbyte)	Block No. (32Kbyte)	Sector No.	Sector Size (Kbytes)	Address Range
64Mb	Block 0	Block 0	Sector 0	4	000000h – 000FFFh
			:	:	:
	Block 1	Block 1	Sector 15	4	00F000h - 00FFFFh
			:	:	:
	Block 1	Block 2	Sector 16	4	010000h – 010FFFh
			:	:	:
	Block 2	Block 3	Sector 31	4	01F000h - 01FFFFh
			:	:	:
	Block 2	Block 4	Sector 32	4	020000h – 020FFFh
			:	:	:
	Block 2	Block 5	Sector 47	4	02F000h – 02FFFFh
			:	:	:
	:	:	:	:	:
	Block 63	Block 126	Sector 1008	4	3F0000h – 3F0FFFh
			:	:	:
	Block 63	Block 127	Sector 1023	4	3FF000h – 3FFFFFFh
			:	:	:
	:	:	:	:	:
	Block 127	Block 254	Sector 2032	4	7F0000h – 7F0FFFh
			:	:	:
	Block 127	Block 255	Sector 2047	4	7FF000h – 7FFFFFFh
			:	:	:

5.2 SERIAL FLASH DISCOVERABLE PARAMETERS

The Serial Flash Discoverable Parameters (SFDP) standard defines the structure of the SFDP database within the memory device. SFDP is the standard of JEDEC JESD216.

The JEDEC-defined header with Parameter ID FF00h and related Basic Parameter Table is mandatory. Additional parameter headers and tables are optional.

Table 5.2 Signature and Parameter Identification Data Values

Description		Address (Byte)	Address (Bit)	Data
SFDP Signature		00h	7:0	53h
		01h	15:8	46h

6. REGISTERS

The device has various sets of Registers: Status, Function, Read, Extended Read and Autboot. When the register is read continuously, the same data is output repeatedly until CE# goes HIGH.

6.1 STATUS REGISTER

Status Register Format and Status Register Bit Definitions are described in Tables 6.1 & 6.2. During power up sequence, volatile register will be loaded with the value of non-volatile value.

Table 6.1 Status Register Format

	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	SRWD	QE	BP3	BP2	BP1	BP0	WEL	WIP
Default	0	0	0	0	0	0	0	0

Table 6.2 Status Register Bit Definition

Bit	Name	Definition	Read-/Write	Type
Bit 0	WIP	Write In Progress Bit: "0" indicates the device is ready (default) "1" indicates a write cycle is in progress and the device is busy	R	Volatile
Bit 1	WEL	Write Enable Latch: "0" indicates the device is not write enabled (default) "1" indicates the device is write enabled	R/W ¹	Volatile
Bit 2	BP0	Block Protection Bit: (See Tables 6.4 for details) "0" indicates the specific blocks are not write-protected (default) "1" indicates the specific blocks are write-protected	R/W	Non-Volatile
Bit 3	BP1			
Bit 4	BP2			
Bit 5	BP3			
Bit 6	QE	Quad Enable bit: "0" indicates the Quad output function disable (default) "1" indicates the Quad output function enable	R/W	Non-Volatile
Bit 7	SRWD	Status Register Write Disable: (See Table 7.1 for details) "0" indicates the Status Register is not write-protected (default) "1" indicates the Status Register is write-protected	R/W	Non-Volatile

Note: WEL bit can be written by WREN and WRDI commands, but cannot by WRSR and VSRWE command.

The BP0, BP1, BP2, BP3, QE, and SRWD are non-volatile and volatile memory cells that can be written by a Write Status Register (WRSR) instruction. The default value of the BP0, BP1, BP2, BP3, QE, and SRWD bits were set to "0" at factory.

The function of Status Register bits are described as follows:

WIP bit: Write In Progress (WIP) is read-only, and can be used to detect the progress or completion of a Program, Erase, Write/Set Non-Volatile/OTP Register, or Gang Sector/Block Lock/Unlock operation. WIP is set to "1" (busy state) when the device is executing the operation. During this time the device will ignore further instructions except for Read Status/Function/Extended Read Register and Software/Hardware Reset instructions. In addition to the instructions, an Erase/Program Suspend instruction also can be executed during a Program or Erase operation. When an operation has completed, WIP is cleared to "0" (ready state) whether the operation is successful or not and the device is ready for further instructions.

WEL bit: Write Enable Latch (WEL) bit indicates the status of the internal write enable latch. When WEL bit is “0”, the internal write enable latch is disabled and the Write operations described in Table 6.3 are inhibited. When WEL bit is “1”, the Write operations are allowed. WEL bit is set by a Write Enable (WREN, 06h) instruction. Most of Write Non-Volatile/Volatile Register, Program and Erase instruction must be preceded by a WREN instruction.

WEL bit can be reset by a Write Disable (WRDI) instruction. It will automatically reset after the completion of any Write Non-Volatile Register, Program and Erase operation.

Table 6.3 Instructions requiring WREN instruction ahead

Instructions must be preceded by the WREN instruction		
Name	Hex Code	Operation
PP	02h	Serial Input Page Program
PPQ	32h/38h	Quad Input Page Program
SER	D7h/20h	Sector Erase 4KB
BER32 (32KB)	52h	Block Erase 32KB
BER64 (64KB)	D8h	Block Erase 64KB
CER	C7h/60h	Chip Erase
WRSR	01h	Write Status Register
WRFR	42h	Write Function Register
SRPNV	65h	Set Read Parameters (Non-Volatile)
SRPV⁽¹⁾	63h	Set Read Parameters (Volatile)
SERPNO	85h	Set Extended Read Parameters (Non-Volatile)
SERPVO	83h	Set Extended Read Parameters (Volatile)
IRER	64h	Erase Information Row
IRP	62h	Program Information Row
WRABR	15h	Write AutoBoot Register
WRDYB	FBh	Write DYB Register
PGPPB	FDh	Write PPB
ERPPB	E4h	Erase PPB
PGASP	2Fh	Program ASP
WRPLB	A6h	Write PPB Lock Bit
SFRZ	91h	Set FREEZE bit
GBLK	7Eh	GANG Sector/Block Lock
GBUN	98h	GANG Sector/Block Unlock
PGPWD	E8h	Program Password

Notes:

1. C0h command for SRPV operation does not require WREN command ahead.

BP3, BP2, BP1, BP0 bits: The Block Protection (BP3, BP2, BP1 and BP0) bits are used to define the portion of the memory area to be protected. Refer to Table 6.4 for the Block Write Protection (BP) bit settings. When a defined combination of BP3, BP2, BP1 and BP0 bits are set, the corresponding memory area is protected. Any program or erase operation to that area will be inhibited.

Note: A Chip Erase (CER) instruction will be ignored unless all the Block Protection Bits are “0”s.

SRWD bit: The Status Register Write Disable (SRWD) bit operates in conjunction with the Write Protection (WP#) signal to provide a Hardware Protection Mode. When the SRWD is set to “0”, the Status Register is not write-protected. When the SRWD is set to “1” and the WP# is pulled low (V_{IL}), the bits of Status Register (SRWD, QE, BP3, BP2, BP1, BP0) become read-only, and a WRSR instruction will be ignored. If the SRWD is set to “1” and WP# is pulled high (V_{IH}), the Status Register can be changed by a WRSR instruction.

QE bit: The Quad Enable (QE) is a non-volatile bit in the Status Register that allows quad operation. When the QE bit is set to “0”, the pin WP# and HOLD#/RESET# are enabled. When the QE bit is set to “1”, the IO2 and IO3 pins are enabled.

WARNING: The QE bit must be set to “0” if WP# or HOLD#/RESET# pin (or ball) is tied directly to the power supply.

Table 6.4 Block (64Kbyte) assignment by Block Write Protect (BP) Bits

Status Register Bits				Protected Memory Area (64Mb, 128Blocks)	
BP3	BP2	BP1	BP0	TBS(T/B selection) = 0, Top area	TBS(T/B selection) = 1, Bottom area
0	0	0	0	0(None)	0(None)

1	0	0	1	7MB	9 (112 blocks : 16 th to 127 th)	9 (112 blocks : 0 th to 111 st)
1	0	1	0	7680KB	10 (120 blocks : 8 th to 127 th)	10 (120 blocks : 0 th to 119 th)
1	0	1	1	7936KB	11 (124 blocks : 4 th to 127 th)	11 (124 blocks : 0 th to 123 rd)
1	1	0	0	8064KB	12 (126 blocks : 2 nd to 127 th)	12 (126 blocks : 0 th to 125 th)
1	1	0	1	8128KB	13 (127 blocks : 1 st to 127 th)	13 (127 blocks : 0 th to 126 th)
1	1	1	0	8MB (All)	14 (128 blocks : 0 th to 127 th)	14 (128 blocks : 0 th to 127 th)
1	1	1	1	8MB (All)	15 (128 blocks : 0 th to 127 th)	15 (128 blocks : 0 th to 127 th)

Notes:

1. x is don't care
2. For Optional BP Table, see the Ordering Information (Option "B")

6.2 FUNCTION REGISTER

Function Register Format and Bit definition are described in Table 6.5 and Table 6.6.

Table 6.5 Function Register Format

	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
	IRL3	IRL2	IRL1	IRL0	ESUS	PSUS	TBS	Dedicated RESET# Disable
Default	0	0	0	0	0	0	0	0 or 1

Table 6.6 Function Register Bit Definition

Bit	Name	Definition	Read /Write	Type
Bit 0	Dedicated RESET# Disable	Dedicated RESET# Disable bit "0" indicates Dedicated RESET# was enabled "1" indicates Dedicated RESET# was disabled	R/W for 0 R for 1	OTP
Bit 1	TBS	Top/Bottom Selection. "0" indicates Top area. "1" indicates Bottom area.	R/W	OTP
Bit 2	PSUS	Program suspend bit: "0" indicates program is not suspend "1" indicates program is suspend	R	Volatile
Bit 3	ESUS	Erase suspend bit: "0" indicates Erase is not suspend "1" indicates Erase is suspend	R	Volatile
Bit 4	IR Lock 0	Lock the Information Row 0: "0" indicates the Information Row can be programmed "1" indicates the Information Row cannot be programmed	R/W	OTP
Bit 5	IR Lock 1	Lock the Information Row 1: "0" indicates the Information Row can be programmed "1" indicates the Information Row cannot be programmed	R/W	OTP
Bit 6	IR Lock 2	Lock the Information Row 2: "0" indicates the Information Row can be programmed "1" indicates the Information Row cannot be programmed	R/W	OTP
Bit 7	IR Lock 3	Lock the Information Row 3: "0" indicates the Information Row can be programmed "1" indicates the Information Row cannot be programmed	R/W	OTP

Note: Once OTP bits of Function Register are written to "1", it cannot be modified to "0" any more.

Dedicated RESET# Disable bit: The default status of the bit is dependent on package type. The device with dedicated RESET# (16-pin SOIC and 24-ball BGA) can be programmed to "1" to disable dedicated RESET# function to move RESET# function to Hold#/RESET# pin (or ball). So the device with dedicated RESET# can be used for dedicated RESET# application and HOLD#/RESET# application.

TBS bit: BP0~3 area assignment can be changed from Top (default) to Bottom by setting TBS bit to "1". However, once Bottom is selected, it cannot be changed back to Top since TBS bit is OTP.

PSUS bit: The Program Suspend Status bit indicates when a Program operation has been suspended. The PSUS changes to "1" after a suspend command is issued during the program operation. Once the suspended Program resumes, the PSUS bit is reset to "0".

ESUS bit: The Erase Suspend Status bit indicates when an Erase operation has been suspended. The ESUS bit is "1" after a suspend command is issued during an Erase operation. Once the suspended Erase resumes, the ESUS bit is reset to "0".

IR Lock bit 0 ~ 3: The default is "0" so that the Information Row can be programmed. If the bit is set to "1", it cannot be changed back to "0" again since IR Lock bits are OTP.

6.3 READ REGISTER

Read Register format and bit definitions are described below. Read Register and Extended Read Register consist of a pair of rewritable non-volatile register and volatile register, respectively. During power up sequence, volatile register will be loaded with the value of non-volatile value.

Table 6.7 and Table 6.8 define all bits that control features in SPI/QPI modes. HOLD#/RESET# pin selection (P7) bit is used to select HOLD# pin or RESET# pin in SPI mode when QE="0" for the device with HOLD#/RESET#. When QE=1 or in QPI mode, P7 bit setting will be ignored since the pin becomes IO3. For 16-pin SOIC or 24-ball TFBGA with dedicated RESET# device (Dedicated RESET# Disable bit in Functional Register is "0"), HOLD# will be selected regardless of P7 bit setting when QE="0" in SPI mode.

The SET READ PARAMETERS Operations (SRPNV: 65h, SRPV: C0h or 63h) are used to set all the Read Register bits, and can thereby define HOLD#/RESET# pin (or ball) selection, dummy cycles, and burst length with wrap around. SRPNV is used to set the non-volatile register and SRPV is used to set the volatile register.

Table 6.7 Read Register Parameter Bit Table

	P7	P6	P5	P4	P3	P2	P1	P0
	HOLD#/RESET#	Dummy Cycles	Dummy Cycles	Dummy Cycles	Dummy Cycles	Wrap Enable	Burst Length	Burst Length
Default	0	0	0	0	0	0	0	0

Table 6.8 Read Register Bit Definition

Bit	Name	Definition	Read-Write	Type
P0	Burst Length	Burst Length	R/W	Non-Volatile and Volatile
P1	Burst Length	Burst Length	R/W	Non-Volatile and Volatile
P2	Burst Length Set Enable	Burst Length Set Enable Bit: "0" indicates disable (default) "1" indicates enable	R/W	Non-Volatile and Volatile
P3	Dummy Cycles	Number of Dummy Cycles: Bits1 to Bit4 can be toggled to select the number of dummy cycles (1 to 15 cycles)	R/W	Non-Volatile and Volatile
P4	Dummy Cycles		R/W	Non-Volatile and Volatile
P5	Dummy Cycles		R/W	Non-Volatile and Volatile
P6	Dummy Cycles		R/W	Non-Volatile and Volatile
P7	HOLD#/RESET#	HOLD#/RESET# function selection Bit: "0" indicates the HOLD# function is selected (default) "1" indicates the RESET# function is selected	R/W	Non-Volatile and Volatile

Table 6.9 Burst Length Data

	P1	P0
8 bytes	0	0
16 bytes	0	1
32 bytes	1	0
64 bytes	1	1

Table 6.10 Wrap Function

Wrap around boundary	P2
Whole array regardless of P1 and P0 value	0
Burst Length set by P1 and P0	1

15	15	166MHz	166MHz	166MHz	166MHz	166MHz	166MHz	80/80MHz	80MHz	80MHz

Notes:
1. Default dummy cycles are as follows.

Operation	Command		Dummy Cycles		Comment
	Normal mode	DTR mode	Normal mode	DTR mode	
Fast Read SPI	0Bh	0Dh	8	8	
Fast Read QPI	0Bh	0Dh	6	6	
Fast Read Dual Output	3Bh	-	8	-	
Fast Read Dual IO SPI	BBh	BDh	4	4	
Fast Read Quad Output	6Bh	-	8	-	
Fast Read Quad IO SPI, QPI	EBh	EDh	6	6	

2. Enough number of dummy cycles must be applied to execute properly the AX read operation.
3. Must satisfy bus I/O contention. For instance, if the number of dummy cycles and AX bits cycles are same, then X must be Hi-Z.
4. QPI mode is not available for FRDDTR command.
5. RDUID, RDSFDP, IRRD operations in SPI mode follow Dummy Cycle setting of Fast Read operation (0Bh).
6. RDUID, IRRD operations in QPI mode follow Dummy Cycle setting of Fast Read operation (0Bh).
7. Maximum frequency for 3.0V device is 133MHz at VDD = 2.30~3.6V, 125°C.
8. Maximum frequency for 1.8V device is 133MHz at VDD = 1.65~1.95V, 125°C.

6.4 EXTENDED READ REGISTER

Table 6.12 and Table 6.13 define all bits that control features in SPI/QPI modes. The ODS2, ODS1, ODS0 (EB7, EB6, EB5) bits provide a method to set and control driver strength. The four bits (EB3, EB2, EB1, EB0) are read-only bits and may be checked to know what the WIP status is or whether there is an error during an Erase, Program, or Write/Set Register operation. These bits are not affected by SERPNV or SERPV commands. EB4 bit remains reserved for future use.

The SET EXTENDED READ PARAMETERS Operations (SERPNV: 85h, SERPV: 83h) are used to set all the Extended Read Register bits, and can thereby define the output driver strength used during READ modes. SRPNV is used to set the non-volatile register and SRPV is used to set the volatile register.

Table 6.12 Extended Read Register Bit Table

	EB7	EB6	EB5	EB4	EB3	EB2	EB1	EB0
	ODS2	ODS1	ODS0	Reserved	E_ERR	P_ERR	PROT_E	WIP
Default	1	1	1	1	0	0	0	0

Table 6.13 Extended Read Register Bit Definition

Bit	Name	Definition	Read-/Write	Type
EB0	WIP	Write In Progress Bit: Has exactly same function as the bit0 (WIP) of Status Register "0": Ready, "1": Busy	R	Volatile
EB1	PROT_E	Protection Error Bit: "0" indicates no error "1" indicates protection error in an Erase or a Program operation	R	Volatile
EB2	P_ERR	Program Error Bit: "0" indicates no error "1" indicates a Program operation failure or protection error	R	Volatile
EB3	E_ERR	Erase Error Bit: "0" indicates no error "1" indicates an Erase operation failure or protection error	R	Volatile
EB4	Reserved	Reserved	R	Reserved
EB5	ODS0	Output Driver Strength: Output Drive Strength can be selected according to Table 6.14	R/W	Non-Volatile and Volatile
EB6	ODS1		R/W	Non-Volatile and Volatile
EB7	ODS2		R/W	Non-Volatile and Volatile

Table 6.14 Driver Strength Table

ODS2	ODS1	ODS0	Description	Remark
0	0	0	Reserved	
0	0	1	12.50%	
0	1	0	25%	
0	1	1	37.50%	
1	0	0	Reserved	
1	0	1	75%	
1	1	0	100%	
1	1	1	50%	Default

WIP bit: The definition of the WIP bit is exactly same as the one of Status Register.

PROT_E bit: The Protection Error bit indicates whether an Erase or Program operation has attempted to modify a protected array sector or block, or to access a locked Information Row region. When the bit is set to “1” it indicates that there was an error or errors in previous Erase or Program operations. See Table 6.15 for details.

P_ERR bit: The Program Error bit indicates whether a Program operation has succeeded or failed, or whether a Program operation has attempted to program a protected array sector/block or a locked Information Row region. When the bit is set to “1” it indicates that there was an error or errors in previous Program or Write/Set Non-Volatile Register operations. See Table 6.15 for details.

E_ERR bit: The Erase Error bit indicates whether an Erase operation has succeeded or failed, or whether an Erase operation has attempted to erase a protected array sector/block or a locked Information Row region. When the bit is set to “1” it indicates that there was an error or errors in previous Erase or Write/Set Non-Volatile Register operations. See Table 6.15 for details.

Table 6.15 Instructions to set PROT_E, P_ERR, or E_ERR bit

Instructions	Description
PP/4PP/PPQ/4PPQ/PGPPB/ 4PGPPB/PGPWD	The commands will set the P_ERR if there is a failure in the operation. Attempting to program within the protected array sector/block or within an erase suspended sector/block will result in a programming error with P_ERR and PROT_E set to “1”.
IRP	The command will set the P_ERR if there is a failure in the operation. In attempting to program within a locked Information Row region, the operation will fail with P_ERR and PROT_E set to 1.
PGASP	The command will set the P_ERR if there is a failure in the operation. Attempting to program ASPR[2:1] after the Protection Mode is selected or attempting to program ASPR[2:1] = 00b will result in a programming error with P_ERR and PROT_E set to “1”.
UNPWD	If the UNPWD command supplied password does not match the hidden internal password, the UNPWD operation fails in the same manner as a programming operation on a protected sector/block and sets the P_ERR and PROT_E to “1”.
WRSR/WRABR/SRPNV/ SERPNV/WRBRNV	The update process for the non-volatile register bits involves an erase and a program operation on the non-volatile register bits. If either the erase or program portion of the update fails, the related error bit (P_ERR or E_ERR) will be set to “1”. Only for WRSR command, when Status Register is write-protected by SRWD bit and WP# pin, attempting to write the register will set PROT_E and E_ERR to “1”.
WRFR	The commands will set the P_ERR if there is a failure in the operation.
SER/4SER/BER32K/ 4BER32K/BER64K/ 4BER64K/CER/IRER/ERPPB	The commands will set the E_ERR if there is a failure in the operation. E_ERR and PROT_E will be set to “1” when the user attempts to erase a protected main memory sector/block or a locked Information Row region. Chip Erase (CER) command will set E_ERR and PROT_E if any blocks are protected by Block Protection bits (BP3~BP0). But Chip Erase (CER) command will not set E_ERR and PROT_E if sectors/blocks are protected by ASP (DYB bits or PPB bits) only.

Notes:

1. OTP bits in the Function Register and TBPARM (OTP bit) in the ASP Register may only be programmed to “1”. Writing of the bits back to “0” is ignored and no error is set.
2. Read only bits and partially protected bits by FREEZE bit in registers are never modified by a command so that the corresponding bits in the Write/Set Register command data byte are ignored without setting any error indication.
3. Once the PROT_E, P_ERR, and E_ERR error bits are set to “1”, they remains set to “1” until they are cleared to “0” with a Clear Extended Read Register (CLERP) command. This means that those error bits must be cleared through the CLERP command. Alternatively, Hardware Reset, or Software Reset may be used to clear the bits.
4. Any further command will be executed even though the error bits are set to “1”.

6.5 AUTOBOOT REGISTER

AutoBoot Register Bit (32 bits) definitions are described in Table 6.16.

Table 6.16 AutoBoot Register Parameter Bit Table

Bits	Symbols	Function	Type	Default Value	Description
AB[31:5]	ABSA	AutoBoot Start Address	Non-Volatile	0000000h	32 byte boundary address for the start of boot code access
AB[4:1]	ABSD	AutoBoot Start Delay	Non-Volatile	0h	Number of initial delay cycles between CE# going low and the first bit of boot code being transferred, and it is the same as dummy cycles of FRD (QE=0) or FRQIO (QE=1). Example: The number of initial delay cycles is 8 (QE=0) or 6 (QE=1) when AB[4:1]=0h (Default setting).
AB0	ABE	AutoBoot Enable	Non-Volatile	0	1 = AutoBoot is enabled 0 = AutoBoot is not enabled

6.6 ADVANCED SECTOR/BLOCK PROTECTION (ASP) RELATED REGISTER

6.6.1 ADVANCED SECTOR/BLOCK PROTECTION REGISTER (ASPR)

Related Commands: Read ASP (RDASP 2Bh) and Program ASP (PGASP 2Fh).

Advanced Sector/Block Protection (ASP) Register Bit (16 bits) definitions are described in Tables 6.19 and 6.20.

Table 6.17 Advanced Sector/Block Protection Register (ASPR) Bit Table

	15	7 to 14	6	5	4	3	2	1	0
	TBPARAM	Reserved	Reserved	Reserved	Reserved	Reserved	PWDMLB	PSTMLB	Reserved
Default	1	1	1	1	1	1	1	1	1

Table 6.18 Advanced Sector/Block Protection Register (ASPR) Bit Definition

Bit	Name	Definition	Read-/Write	Type
0	Reserved	Reserved	R	Reserved
1	PSTMLB	Persistent Protection Mode Lock Bit "0" = Persistent Protection Mode permanently enabled. "1" = Persistent Protection Mode not permanently enabled.	R/W	OTP
2	PWDMLB	Password Protection Mode Lock Bit "0" = Password Protection Mode permanently enabled. "1" = Password Protection Mode not permanently enabled.	R/W	OTP
14:3	Reserved	Reserved	R	Reserved
15	TBPARAM	Configures Parameter Sectors location "0" = 4KB physical sectors at top, (high address) "1" = 4KB physical sectors at bottom (Low address)	R/W	OTP

The Advanced Sector/Block Protection Register (ASPR) is used to permanently configure the behavior of Advanced Sector/Block Protection (ASP) features and parameter sectors location.

PWDMLB (ASPR[2]) and PSTMLB (ASPR[1]) bits: When shipped from the factory, all devices default ASP to the Persistent Protection Mode, with all sectors unprotected, when power is applied. The device programmer or host system must then choose which sector/block protection method to use. Programming either of the Protection Mode Lock Bits locks the part permanently in the selected mode:

- ASPR[2:1] = 11 = No ASP mode selected, Persistent Protection Mode is the default.
- ASPR[2:1] = 10 = Persistent Protection Mode permanently selected.
- ASPR[2:1] = 01 = Password Protection Mode permanently selected.
- ASPR[2:1] = 00 = Illegal condition, attempting to program both bits to zero results in a programming failure and the program operation will abort. It will result in a programming error with P_ERR set to 1.

As a result, PWDMLB and PSTMLB are mutually exclusive, only one may be programmed to zero.

ASPR programming rules:

- If the Password Protection Mode is chosen, the password must be programmed prior to setting the corresponding bit.
- Once the Protection Mode is selected, the ASPR[2:1] bits are permanently protected from programming and no further change to the ASPR[2:1] is allowed. Attempting to program ASPR[2:1] after selected will result in a programming error with P_ERR set to 1. The programming time of the ASPR is the same as the typical page programming time. The system can determine the status of the ASPR programming operation by reading the WIP bit in the Status Register or Extended Read Register.
- TBPARAM bit can be programmed even after ASPR[2:1] bits are programmed while the FREEZE bit in the PPB Lock Register is "0".

TBPARM bit: TBPARM defines the logical location of the parameter block. The parameter block consists of thirty-two 4KB sectors, which replace two 64KB blocks. When TBPARM is default state (“1”), the parameter block is at the Bottom of the array. When TBPARM is programmed to “0”, the parameter block is in the top of the memory array address space. TBPARM is OTP and default state “1” when it ships from Factory. If TBPARM is programmed to “0”, an attempt to change it back to “1” will fail and ignore the Program.

The desired state of TBPARM must be selected during the initial configuration of the device during system manufacture; before the first program or erase operation on the main flash array. TBPARM must not be programmed after programming or erasing is done in the main flash array.

TBS bit in the Function Register can be programmed independent of TBPARM. Therefore, the user can select to store parameter information from the bottom of the array and protect boot code starting at the top of the array, and vice versa. Or the user can select to store and protect the parameter information starting from the top or bottom together.

6.6.2 PASSWORD REGISTER

Related Commands: Read Password (RDPWD E7h), Program Password (PGPWD E8h), and Unlock Password (UNPWD, E9h).

Table 6.19 Password Register Bit Definition

Bit	Name	Definition	Default	Read-/Write	Type
63:0	PSWD	64 bit hidden password: The password is no longer readable after the password protection mode is selected by programming ASPR bit 2 to zero.	FFFFFFFF- FFFFFFFFh	R/W	OTP

6.6.3 PPB LOCK REGISTER

Related Commands: Read PPB Lock Bit (RDPLB A7h), Write PPB Lock Bit (WRPLB A6h), UNPWD (E9h) and Set FREEZE Bit (SFRZ 91h).

Table 6.20 PPB Lock Register Bit Definition

Bit	Name	Definition	Default	Read-/Write	Type
0	PPBLK	PPB Lock bit: Protect PPB Array “0” = PPB array protected until next power cycle or Hardware Reset “1” = PPB array may be programmed or erased.	Persistent: 1 Password: 0	R/W	Volatile
6:1	Reserved	Reserved	Reserved	R	Reserved
7	FREEZE	Lock current state of BP3-0 bits in Status Register, TBS in Function Register and TBPARM in ASPR, and Information Row (IR) regions. “1” = Locked “0” = Un-locked	0	R/W	Volatile

PPBLK bit: The PPB Lock bit is a volatile bit for protecting all PPB bits. When cleared to 0, it locks all PPBs, when set to “1”, it allows the PPBs to be changed. The WRPLB command is used to clear the PPB Lock bit to “0”. The PPB Lock bit must be cleared to 0 only after all the PPBs are configured to the desired settings.

In Persistent Protection mode, the PPB Lock bit is set to “1” during POR or Hardware Reset. The PPB Lock bit can only be cleared to “0” by the Write PPB Lock Bit (WRPLB A6h) command only. When cleared to “0”, no software command sequence can set the PPB Lock bit back to “1”, only another Hardware Reset or power-up can set the PPB Lock bit.

In the Password Protection mode, the PPB Lock bit is cleared to 0 during POR or Hardware Reset. The PPB Lock bit can only be set to 1 by the Unlock Password command only. When set to “1”, no software command sequence can clear the PPB Lock bit back to “0”, only another Hardware Reset or power-up can clear the PPB Lock bit.

FREEZE bit: FREEZE bit, when set to “1”, locks the current state of BP3-0 in Status Register, TBS in the Function Register, TBPARM in the Advanced Sector/Block Protection Register, and the Information Row. This prevents writing, programming, or erasing these areas. As long as FREEZE remains cleared to logic “0”, BP3-0 in Status Register, TBS in the Function Register, and TBPARM in the Advanced Sector/Block Protection Register are writable and the Information Row is programmable. Once FREEZE has been written to a logic “1” it can only be cleared to a logic “0” by a power-on cycle or a Hardware Reset. Software Reset will not affect the state of FREEZE. The FREEZE is volatile and the default state of FREEZE after power-on is “0”. The FREEZE can be set to “1” by a SFRZ command only.

6.6.4 PPB REGISTER

Related Commands: Read PPB (RDPPB, FCh) Program PPB (PGPPB, FDh), and Erase PPB (ERPPB, E4h).

Table 6.21 PPB Register Bit Definition

Bit	Name	Definition	Default	Read-/Write	Type
7:0	PPB	Read or Program per sector/block PPB: 00h = PPB for the sector/block addressed by the RDPPB or PGPPB command is programmed to “0”, protecting that sector/block from program or erase operations. FFh = PPB for the sector/block addressed by the RDPPB or PGPPB command is erased to “1”, not protecting that sector/block from program or erase operations.	FFh	R/W	Non-Volatile

6.6.5 DYB REGISTER

Related Commands: Read DYB (RDDYB, FAh) and Write DYB (WRDYB, FBh).

Table 6.22 DYB Register Bit Definition

Bit	Name	Definition	Default	Read-/Write	Type
7:0	DYB	Read or Write per sector/block DYB: 00h = DYB for the sector/block addressed by the RDDYB or WRDYB command is cleared to “0”, protecting that sector/block from program or erase operations. FFh = DYB for the sector/block addressed by the RDDYB or WRDYB command is set to “1”, not protecting that sector/block from program or erase operations.	FFh	R/W	Volatile

7. PROTECTION MODE

The device supports hardware and software write-protection mechanisms.

7.1 HARDWARE WRITE PROTECTION

The Write Protection (WP#) pin provides a hardware write protection method for BP3, BP2, BP1, BP0, SRWD, and QE in the Status Register. Refer to the section 6.1 STATUS REGISTER.

Write inhibit voltage (V_{WI}) is specified in the section 9.7 POWER-UP AND POWER-DOWN. All write sequence will be ignored when V_{CC} drops to V_{WI} .

Table 7.1 Hardware Write Protection on Status Register

SRWD	WP#	Status Register
0	Low	Writable
1	Low	Protected
0	High	Writable
1	High	Writable

Note: Before the execution of any program, erase or Write Status/Function Register instruction, the Write Enable Latch (WEL) bit must be enabled by executing a Write Enable (WREN) instruction. If the WEL bit is not enabled, the program, erase or write register instruction will be ignored.

7.2 SOFTWARE WRITE PROTECTION

The device also provides two kinds of software write protection feature. One is Block Protection by Block Protection bits (BP3, BP2, BP1, BP0) and another is Advanced Sector/Block Protection (ASP). When Block Protection is enabled (i.e., any BP3-0 are set to "1"), Advanced Sector/Block Protection (ASP) can still be used to protect sectors/blocks not protected by the Block Protection scheme. In the case that both ASP and Block Protection are used on the same sector/block the logical OR of ASP and Block Protection related to the sector/block is used.

7.2.1 BLOCK PROTECTION BITS

The device provides a software write protection feature. The Block Protection bits (BP3, BP2, BP1, BP0) allow part or the whole memory area to be write-protected. For details, see 6.1 Status Register.

7.2.2 ADVANCED SECTOR/BLOCK PROTECTION (ASP)

There are two ways to implement software Advanced Sector/Block Protection on this device: Password Protection method or Persistent Protection methods. Through these two protection methods, user can disable or enable the programming or erasing operation to any or all blocks including 32 top 4K sectors or 32 bottom 4K sectors. The Figure 7.1 shows an overview of these methods.

Every main flash array block/top sector/bottom sector has a non-volatile (PPB) and a volatile (DYB) protection bit associated with it. When either bit is 0, the sector is protected from program and erase operations.

The PPB bits are protected from program and erase when the PPB Lock bit is “0”. The PPB bits are erased so that all main flash array sectors are unprotected when shipped from factory.

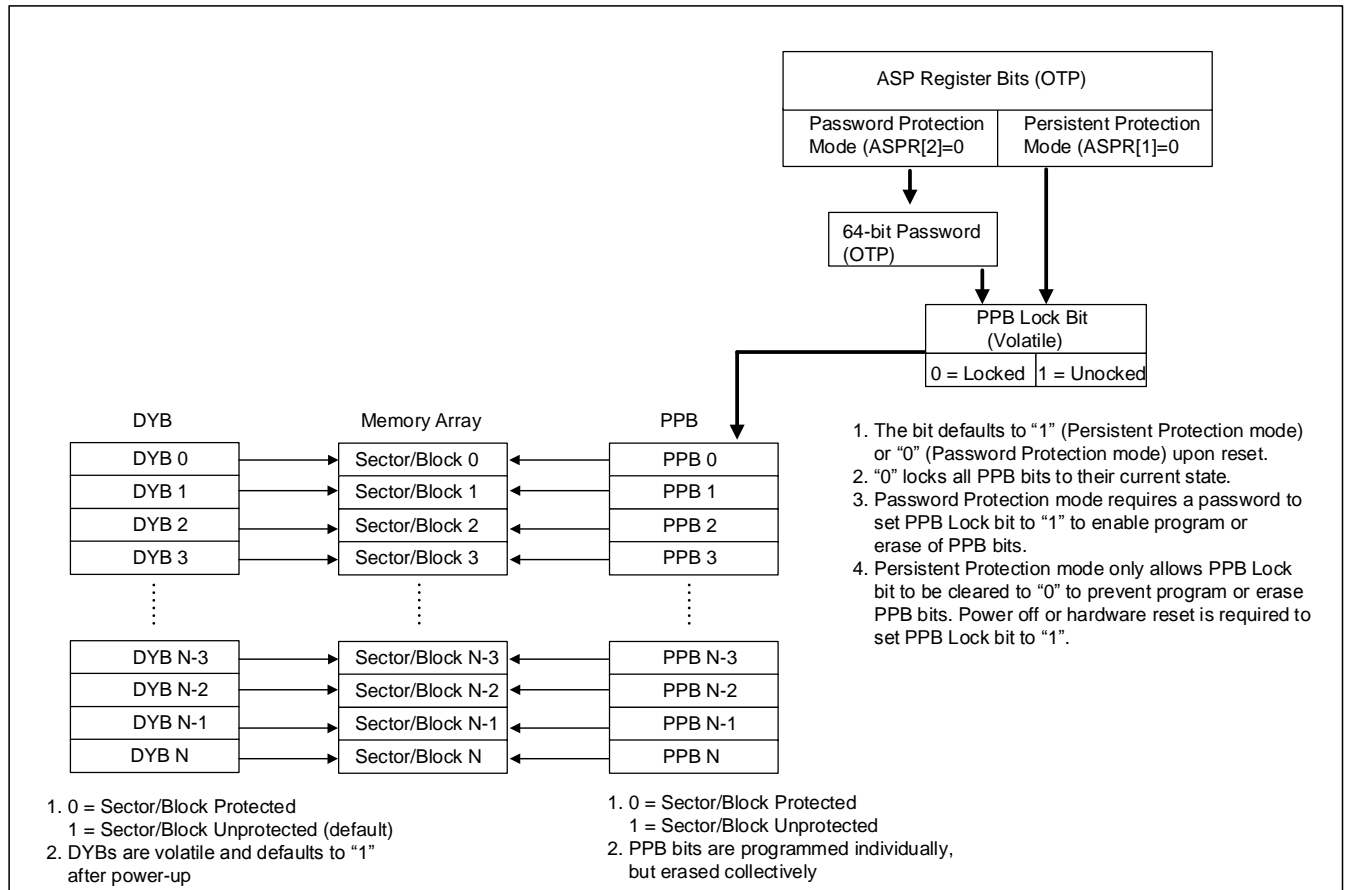

There are two methods for managing the state of the PPB Lock bit, Persistent Protection and Password Protection.

The Persistent Protection Mode sets the PPB Lock bit to “1” during power up or Hardware Reset so that the PPB bits are unprotected. There is a WRPLB command to clear the PPB Lock bit to “0” to protect the PPB bits. There is no command in the Persistent Protection method to set the PPB Lock bit therefore the PPB Lock bit will remain at “0” until the next power up or Hardware Reset. The Persistent Protection method allows boot code the option of changing sector protection by programming or erasing the PPB, then protecting the PPB from further change for the remainder of normal system operation by clearing the PPB Lock bit. This is sometimes called Boot-code controlled sector protection.

The Password Protection Mode requires use of a password to control PPB protection. In the Password Protection Mode, the PPB Lock bit is cleared to “0” during power up or Hardware Reset to protect the PPB bits. A 64-bit password may be permanently programmed and hidden for the Password Protection Mode. The UNPWD command can be used to provide a password for comparison with the hidden password. If the password matches the PPB Lock bit is set to “1” to unprotect the PPB. The WRPLB command can be used to clear the PPB Lock bit to “0”. After clearing the PPB Lock bit to “0”, the UNPWD command can be used again to unprotect the PPB.

The selection of the PPB Lock bit management method is made by programming OTP bits in the ASP Register so as to permanently select the method used.

Figure 7.1 Advanced Sector/Block Protection

Note: 64M: N = 157 = 32 (32xTop 4K sectors or 32xBottom 4K sectors) + 126 (254x64K blocks) - 1

Table 7.2 PPB/DYB and Sector/Block mapping (TBPARM = 1)

Memory Density	PPB Group	DYB Group	Block No. (64Kbyte)	Sector No.	Sector Size (Kbyte)	Address Range

			:	:	:	
			:	:	:	

Persistent Protection Bits (PPBs)

The Persistent Protection Bits (PPBs) are unique for each sector/block and non-volatile (refer to Figure 7.1, Table 7.2, and Table 7.3). It is programmed individually but must be erased as a group, similar to the way individual words may be programmed in the main array but an entire sector/block must be erased at the same time. The PPBs have the same endurance as the Flash memory. Preprogramming and verification prior to erasure are handled by the device, and therefore do not require system monitoring. Programming a PPB bit requires the typical page programming time. Erasing all the PPBs requires typical sector erase time. During PPB bit programming and PPB bit erasing, status is available by reading the Status Register or Extended Read Register. Reading of a PPB bit requires the initial access time of the device.

Notes:

1. Each PPB is individually programmed to “0” and all are erased to “1” in parallel.
2. The PPB Lock bit must be cleared first before changing the status of a PPB.
3. While programming PPB, array data cannot be read from any sectors/blocks.
4. When reading the PPB of the desired sector/block the address should be location zero within the sector/block. The high order address bits not used must be zero.
5. There are no means for individually erasing a specific PPB and no specific sector/block address is required for this operation.
6. The state of the PPB for a given sector/block can be verified by using a PPB Read command.
7. When the parts are first shipped, the PPBs are cleared (erased to “1”).

Dynamic Protection Bits (DYBs)

Dynamic Protection Bits (DYBs) are volatile and unique for each sector/block and can be individually modified. DYBs only control the protection for unprotected sectors/blocks that have their PPBs cleared (erased to “1”). By issuing the Write DYB command, the DYBs are cleared to “0” or set to “1”, thus placing each sector/block in the protected or unprotected state respectively. This feature allows software to easily protect sectors/blocks against inadvertent changes, yet does not prevent the easy removal of protection when changes are needed. The DYBs can be set or cleared as often as needed as they are volatile bits.

Persistent Protection Bit (PPB) Lock Bit

The PPB Lock bit is a volatile bit for protecting all PPB bits. When cleared to “0”, it locks all PPBs and when set to “1”, it allows the PPBs to be changed. . If the PPB Lock bit is “0”, the PPB Program or Erase command does not execute and fails without programming or erasing the PPB.

In Persistent Protection mode, the PPB Lock bit is set to “1” during power up or Hardware Reset. When cleared to “0”, no software command sequence can set the PPB Lock bit to “1”, only another Hardware Reset or power-up can set the PPB Lock bit.

In the Password Protection mode, the PPB Lock bit is cleared to “0” during power up or a Hardware Reset during power up or a Hardware Reset. The PPB Lock bit can only be set to “1” by the Password Unlock command.

The PPB Lock bit must be cleared to “0” only after all PPBs are configured to the desired settings.

Sector/Block Protection States Summary

Each sector in specific blocks and each of all other blocks except for the specific blocks can be in one of the following protection states:

- Unlocked – The sector/block is unprotected and protection can be changed by a simple command. The protection state defaults to unprotected after a power cycle, software reset, or hardware reset.
- Dynamically Locked – A sector/block is protected and protection can be changed by a simple command. The protection state is not saved across a power cycle.
- Persistently Locked – A sector/block is protected and protection can only be changed if the PPB Lock bit is set to “1”. The protection state is non-volatile and saved across a power cycle or reset. Changing the protection state requires programming and or erase of the PPB bits.

Table 7.4 contains all possible combinations of the DYB, PPB, and PPB Lock bit relating to the status of the sector/block. In summary, if the PPB Lock bit is locked (cleared to “0”), no changes to the PPBs are allowed. The PPB Lock bit can only be unlocked (set to “1”) through a Hardware Reset or power cycle.

Table 7.4 Sector/Block Protection States

		Protection Bit values		Assigned Sector/Block State
		PPB	DYB	
“0” = Locked or Protected “1” = Unlocked or Unprotected		1	1	Unprotected
		1	0	Protected
		0	1	Protected
		0	0	Protected
PPB Lock Bit	1	Changeable	Changeable	/
	0	NOT changeable	Changeable	

Persistent Protection Mode

The Persistent Protection Mode sets the PPB Lock bit to “1” during power up or Hardware Reset so that the PPB bits are unprotected by a device Hardware Reset. Software Reset does not affect the PPB Lock bit. The WRPLB command can clear the PPB Lock bit to “0” to protect the PPB. There is no command to set the PPB Lock bit therefore the PPB Lock bit will remain at “0” until the next power up or Hardware Reset.

Password Protection Mode

The Password Protection Mode allows an even higher level of security than the Persistent Protection Mode by requiring a 64-bit password for unlocking the device PPB Lock bit. In addition to this password requirement, after power up or Hardware Reset, the PPB Lock bit is cleared to “0” to maintain the password mode of operation. Successful execution of the Unlock Password command by entering the entire password sets the PPB Lock bit to “1”, allowing for sector/block PPBs modifications.

Notes:

1. The password is all “1”s when shipped from Factory. It is located in its own memory space and is accessible through the use of the Program Password and Read Password commands.
2. Once the Password is programmed and verified, the Password Protection Mode Lock Bit (ASPR[2]=0) in ASP Register must be programmed in order to prevent reading or modifying the password. After the Password Protection Mode Lock Bit is programmed, all further Program and Read commands to the password region are disabled and these commands are ignored so that there is no means to verify what the password is. Password verification is only allowed before selecting the Password Protection Mode.
3. The Program Password Command is only capable of programming “0”s. Programming a “1” after a cell is programmed as a “0” results in the cell left as a “0” with no programming error.
4. All 64-bit password combinations are valid as a password.
5. The Protection Mode Lock Bits in ASP Register are not erasable because they are OTP.
6. The exact password must be entered in order for the unlocking function to occur. If the password provided by Unlock Password command does not match the hidden internal password, the unlock operation fails in the same manner as a programming operation on a protected sector/block. The P_ERR and PROT_E are set to 1 and the PPB Lock bit remains cleared to 0. In this case it is a failure to change the state of the PPB Lock bit because it is still protected by the lack of a valid password.
7. The Unlock Password command cannot be accepted any faster than once every $100\mu\text{s} \pm 20\mu\text{s}$. This makes it take an unreasonably long time (58 million years) for a hacker to run through all the 64-bit combinations in an attempt to correctly match a password. The Read Status Register command or the Read Extended Read Register may be used to read the WIP bit to determine when the device has completed the Unlock Password command or is ready to accept a new password command. When a valid password is provided the Unlock Password command does not insert the $100\mu\text{s}$ delay before returning the WIP bit to zero.
8. If the password is lost after selecting the Password Protection Mode, there is no way to set the PPB Lock bit.

8. DEVICE OPERATION

8.1 COMMAND OVERVIEW

The device utilizes an 8-bit instruction register. Refer to Table 8.3. Instruction Set for details on instructions and instruction codes. All instructions, addresses, and data are shifted in with the most significant bit (MSB) first on Serial Data Input (SI) or Serial Data IOs (IO0, IO1, IO2, IO3). The input data on SI or IOs is latched on the rising edge of Serial Clock (SCK) for normal mode and both of rising and falling edges for DTR mode after Chip Enable (CE#) is driven low (V_{IL}). Every instruction sequence starts with a one-byte instruction code and is followed by address bytes and/or dummy cycles (configurable) and/or data bytes, depending on the type of instruction. CE# must be driven high (V_{IH}) after the last bit of the instruction sequence has been shifted in to end the operation.

Commands are structured as follows:

- Each command begins with a byte (eight bits) instruction.
- The instruction may be stand alone or may be followed by address bits to select a location within one of several address spaces in the device. The address may be either a 24-bit or 32-bit byte boundary address.
- The SPI interface with Multiple IO provides the option for each transfer of address and data information to be done one, two, or four bits in parallel. This enables a tradeoff between the number of signal connections (IO bus width) and the speed of information transfer. If the host system can support a two or four bit wide IO bus the memory performance can be increased by using the instructions that provide parallel two bit (dual) or parallel four bit (quad) transfers.
- The width of all transfers following the instruction are determined by the instruction sent.
- All single bit or parallel bit groups are transferred in most to least significant bit order.
- Some instructions send Mode Bits following the address to indicate that the next command will be of the same type with an implied, rather than an explicit, instruction. The next command thus does not provide an instruction byte, only a new address and mode bits. This reduces the time needed to send each command when the same command type is repeated in a sequence of commands.
- The address or Mode Bits may be followed by Dummy Cycles before read data is returned to the host.
- Dummy Cycles may be zero to several SCK cycles. In fact, Mode Bits will be counted as a part of Dummy Cycles.
- All instruction, address, Mode, and data information is transferred in byte granularity. Addresses are shifted into the device with the Most Significant Byte first. All data is transferred with the lowest address byte sent first. Following bytes of data are sent in lowest to highest byte address order i.e. the byte address increments.
- All attempts to read the flash memory array during a program, erase, or a write cycle (embedded operations) are ignored. The embedded operation will continue to execute without any affect. A very limited set of commands are accepted during an embedded operation. These are discussed in the individual command descriptions. While a program, erase, or write operation is in progress, it is recommended to check that the Write In Progress (WIP) bit is "0" before issuing most commands to the device, to ensure the new command can be accepted.
- Depending on the command, the time for execution varies. A command to read status information from an executing command is available to determine when the command completes execution and whether the command was successful.
- Following are some general signal relationship descriptions to keep in mind.
 - The host always controls the Chip Enable (CE#), Serial Clock (SCK), and Serial Input (SI) - SI for single bit wide transfers. The memory drives Serial Output (SO) for single bit read transfers. The host and memory alternately drive the IO0-IO3 signals during Dual and Quad transfers.
 - All commands begin with the host selecting the memory by driving CE# low before the first rising edge of SCK. CE# is kept low throughout a command and when CE# is returned high the command ends. Generally, CE# remains low for 8-bit transfer multiples to transfer byte granularity information. All commands will not be accepted if CE# is returned high not at an 8-bit boundary.

8.2 COMMAND SET SUMMARY
Table 8.1 All Instruction Set

Instruction Name	Operation	Mode	Byte0	Byte1	Byte2	Byte3	Byte4	Byte5	Byte6
NORD	Normal Read Mode (3-byte Address)	SPI	03h	A <23:16>	A <15:8>	A <7:0>	Data out		
FRD	Fast Read Mode (3-byte Address)	SPI QPI	0Bh	A <23:16>	A <15:8>	A <7:0>	Dummy ⁽¹⁾ Byte	Data out

GBUN	Clear all DYB bits (Gang Sector/ Block Unlock)	SPI QPI	98h						

Notes:

1. The number of dummy cycles are programmable, and table shows default dummy default dummy cycles.
2. AXh has to be counted as a part of dummy cycles. X means "don't care".
3. XX means "don't care".
4. A<23:9> are "don't care" and A<8:4> are always "0".

8.3 NORMAL READ OPERATION (NORD, 03h)

The Normal Read (NORD) instruction is used to read memory contents at a maximum frequency of 80MHz.

The Normal Read instruction code is transmitted via the SI line, followed by three (A23 - A0) address bytes of the first memory location to be read as above. A total of 24 address bits are shifted in, but only A_{VM}SB (Valid Most Significant Bit: A₂₂) - A₀ are decoded. The remaining bit (A₂₃) is ignored. The first byte addressed can be at any memory location. Upon completion, any data on the SI will be ignored.

The first byte data (D7 - D0) is shifted out on the SO line, MSB first. A single byte of data, or up to the whole memory array, can be read out in one Normal Read instruction. The address is automatically incremented by one after each byte of data is shifted out. The read operation can be terminated at any time by driving CE# high (VIH) after the data comes out. When the highest address of the device is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read in one continuous Read instruction.

If the Normal Read instruction is issued while an Erase, Program or Write operation is in process (WIP=1) the instruction is ignored and will not have any effects on the current operation.

Figure 8.1 Normal Read Sequence (03h)

8.4 FAST READ OPERATION (FRD, 0Bh)

The FAST READ (FRD) instruction is used to read memory data.

The FAST READ instruction code is followed by three address bytes (A23 - A0) and dummy cycles (configurable, default is 8 clocks), transmitted via the SI line, with each bit latched-in during the rising edge of SCK. Then the first data byte from the address is shifted out on the SO line, with each bit shifted out at a maximum frequency f_{CT} , during the falling edge of SCK.

The first byte addressed can be at any memory location. The address is automatically incremented by one after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FAST READ instruction. The FAST READ instruction is terminated by driving CE# high (VIH).

If the FAST READ instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored without affecting the current cycle.

Figure 8.2 Fast Read Sequence (0Bh)

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

FAST READ OPERATION IN QPI MODE (FRD, 0Bh)

The FAST READ (FRD) instruction is used also in QPI mode to read memory data.

The FAST READ instruction code (2 clocks) is followed by three address bytes (A23-A0 — 6 clocks) and dummy cycles (configurable, default is 6 cycles), transmitted via the IO3, IO2, IO1 and IO0 lines, with each bit latched-in during the rising edge of SCK. Then the first data byte addressed is shifted out on the IO3, IO2, IO1 and IO0 lines, with each bit shifted out at a maximum frequency f_{CT} , during the falling edge of SCK.

The first byte addressed can be at any memory location. The address is automatically incremented by one after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FAST READ instruction. The FAST READ instruction in QPI mode is terminated by driving CE# high (VIH).

If the FAST READ instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored without affecting the current cycle.

The Fast Read sequence in QPI mode is also applied to the commands in the following table.

Table 8.2 Instructions that Fast Read sequence in QPI Mode is applied to

Instruction Name	Operation	Hex Code
FRQIO	Fast Read Quad I/O	EBh
RDUID	Read Unique ID	4Bh
IRRD	Read Information Row	68h

Figure 8.3 Fast Read Sequence In QPI Mode

Note: Number of dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

8.5 HOLD OPERATION

HOLD# is used in conjunction with CE# to select the device. When the device is selected and a serial sequence is underway, HOLD# can be used to pause the serial communication with the master device without resetting the serial sequence. To pause, HOLD# is brought low while the SCK signal is low. To resume serial communication, HOLD# is brought high while the SCK signal is low (SCK may still toggle during HOLD). Inputs to SI will be ignored while SO is in the high impedance state, during HOLD.

Note: HOLD is not supported in DTR mode or with QE=1 or when RESET# is selected for the HOLD# or RESET# pin.

Timing graph can be referenced in AC Parameters Figure 9.4.

8.6 FAST READ DUAL I/O OPERATION (FRDIO, BBh)

The FRDIO allows the address bits to be input two bits at a time. This may allow for code to be executed directly from the SPI in some applications.

The FRDIO instruction code is followed by three address bytes (A23 – A0) and dummy cycles (configurable, default is 4 clocks), transmitted via the IO1 and IO0 lines, with each pair of bits latched-in during the rising edge of SCK. The address MSB is input on IO1, the next bit on IO0, and this shift pattern continues to alternate between the two lines. Depending on the usage of AX read operation mode, a mode byte may be located after address input.

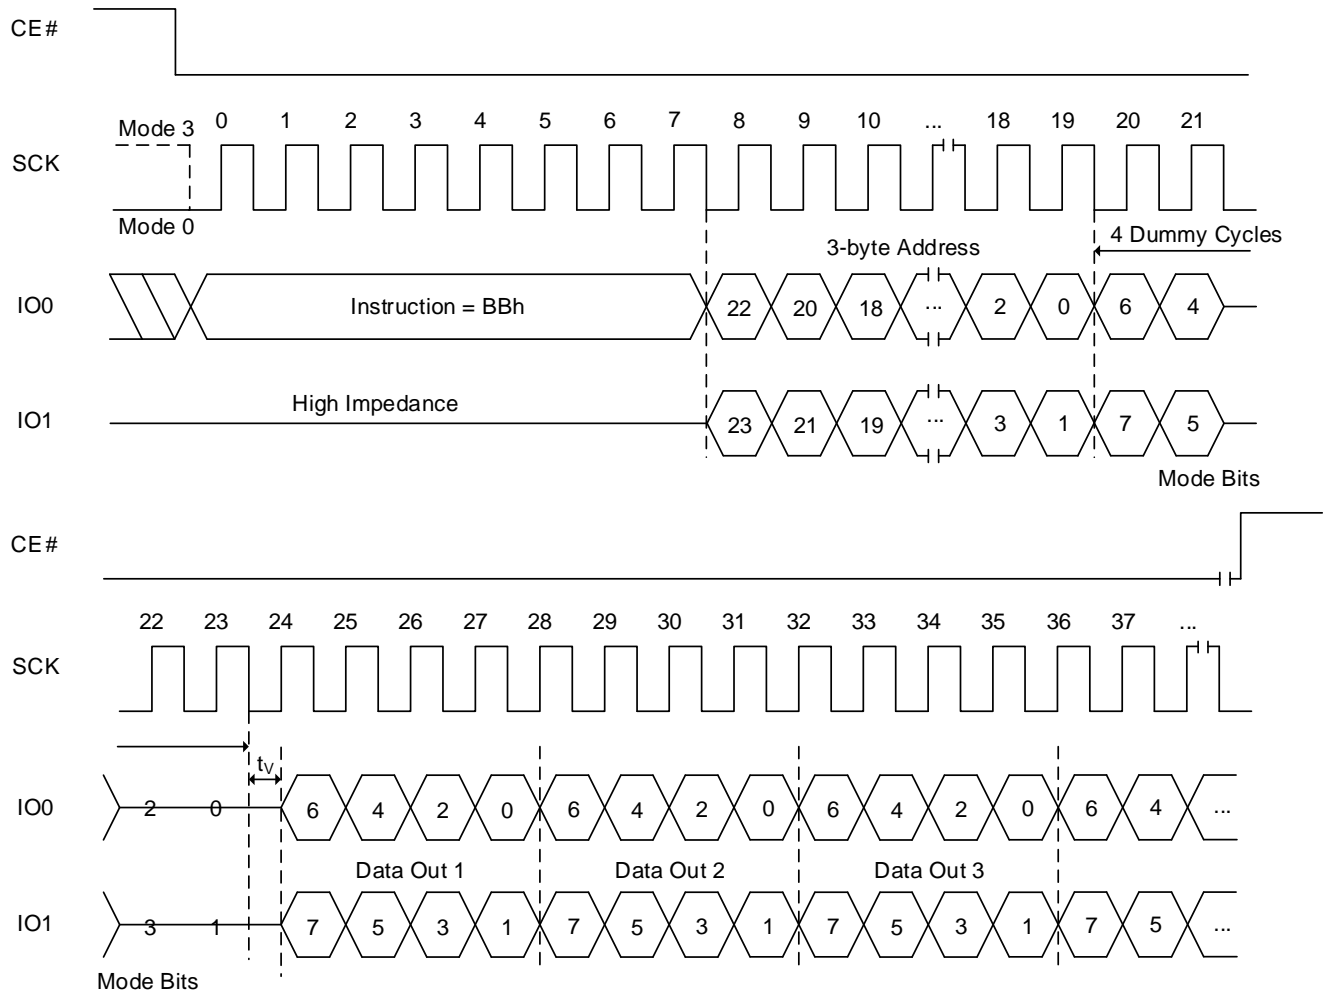

The first data byte addressed is shifted out on the IO1 and IO0 lines, with each pair of bits shifted out at a maximum frequency f_{CT} , during the falling edge of SCK. The MSB is output on IO1, while simultaneously the second bit is output on IO0. Figure 8.4 illustrates the timing sequence.

The first byte addressed can be at any memory location. The address is automatically incremented by one after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FRDIO instruction. FRDIO instruction is terminated by driving CE# high (V_{IH}).

The device supports the AX read operation by applying mode bits during dummy period. Mode bits consist of 8 bits, such as M7 to M0. Four cycles after address input are reserved for Mode bits in FRDIO execution. M7 to M4 are important for enabling this mode. M3 to M0 become don't care for future use. When M[7:4]=1010(Ah), it enables the AX read operation and subsequent FRDIO execution skips command code. It saves cycles as described in Figure 8.5. When the code is different from AXh (where X is don't care), the device exits the AX read operation. After finishing the read operation, device becomes ready to receive a new command. SPI or QPI mode configuration retains the prior setting. Mode bit must be applied during dummy cycles. Number of dummy cycles in Table 6.11 includes number of mode bit cycles. If dummy cycles are configured as 4 cycles, data output will start right after mode bit is applied.

If the FRDIO instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not affect the current cycle.

Figure 8.4 Fast Read Dual I/O Sequence (BBh)

Notes:

1. If the mode bits=AXh (where X is don't care), it can execute the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

Figure 8.5 Fast Read Dual I/O AX Read Sequence (without command decode cycles)

Notes:

1. If the mode bits=AXh (where X is don't care), it will keep executing the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

8.7 FAST READ DUAL OUTPUT OPERATION (FRDO, 3Bh)

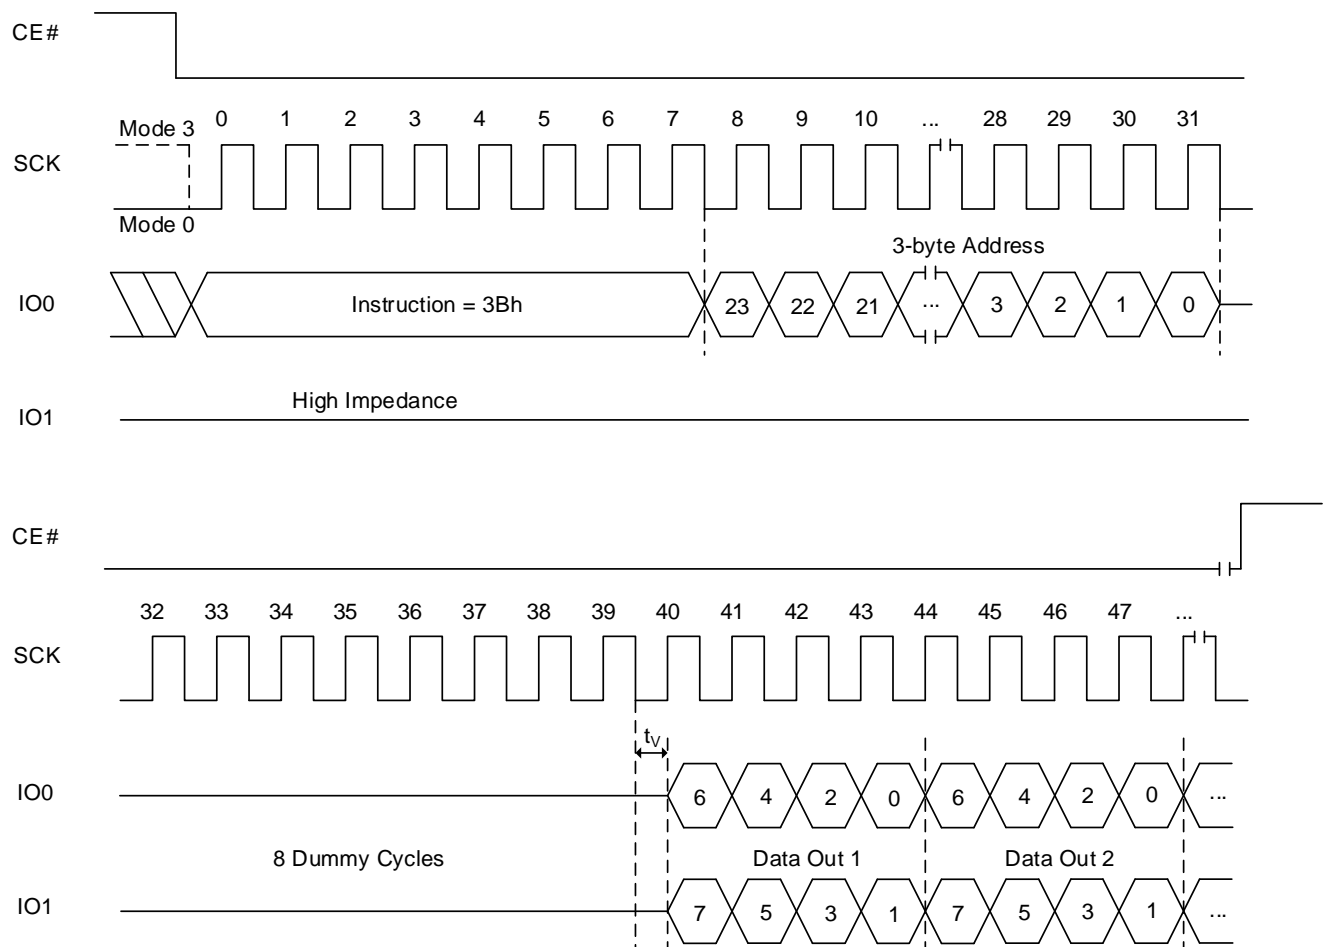

The FRDO instruction is used to read memory data on two output pins.

The FRDO instruction code is followed by three address bytes (A23 – A0) and dummy cycles (configurable, default is 8 clocks), transmitted via the IO0 line, with each bit latched-in during the rising edge of SCK. Then the first data byte addressed is shifted out on the IO1 and IO0 lines, with each pair of bits shifted out at a maximum frequency f_{CT} , during the falling edge of SCK. The first bit (MSB) is output on IO1. Simultaneously, the second bit is output on IO0.

The first byte addressed can be at any memory location. The address is automatically incremented by one after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FRDO instruction. The FRDO instruction is terminated by driving CE# high (VIH).

If the FRDO instruction is issued while an Erase, Program or Write cycle is in process (BUSY=1) the instruction is ignored and will not have any effects on the current cycle.

Figure 8.6 Fast Read Dual Output Sequence (3Bh)

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

8.8 FAST READ QUAD OUTPUT OPERATION (FRQO)

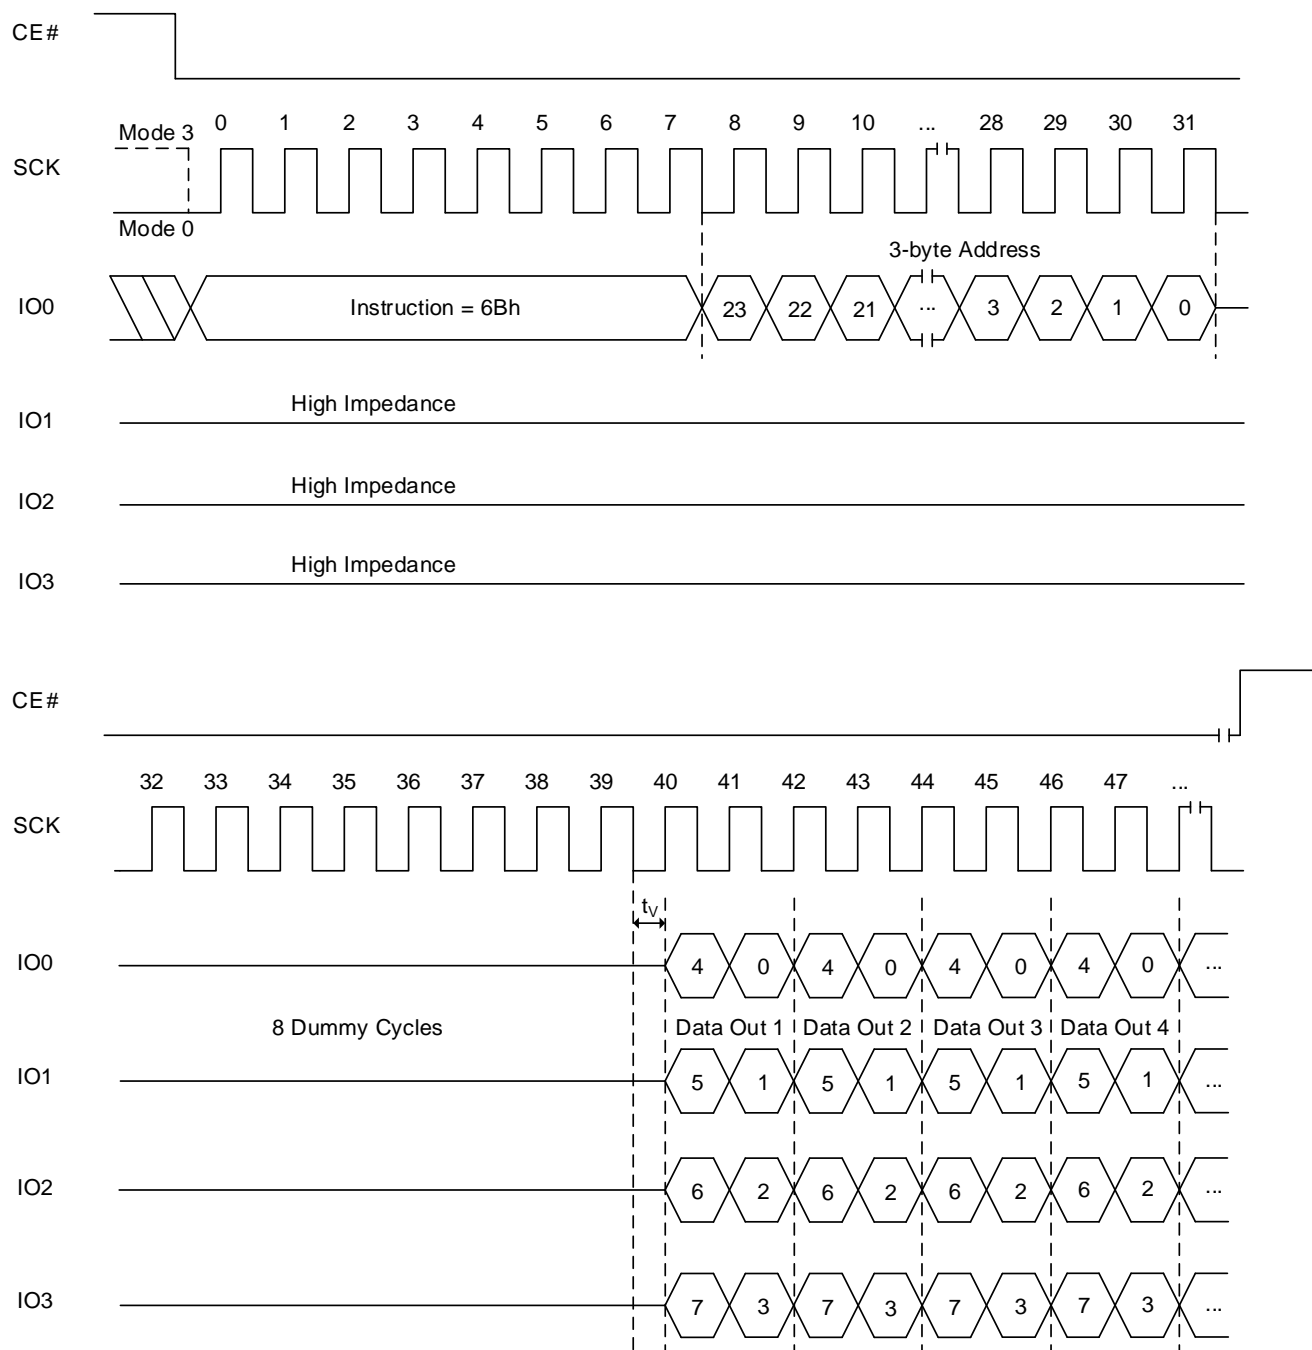

The FRQO instruction is used to read memory data on four output pins. A Quad Enable (QE) bit of status Register must be set to “1” before sending FRQO instruction.

The FRQO instruction code is followed by three address bytes (A23 – A0) and dummy cycles (configurable, default is 8 clocks), transmitted via the IO0 line, with each bit latched-in during the rising edge of SCK. Then the first data byte addressed is shifted out on the IO3, IO2, IO1 and IO0 lines, with each group of four bits shifted out at a maximum frequency fCT, during the falling edge of SCK. The first bit (MSB) is output on IO3, while simultaneously the second bit is output on IO2, the third bit is output on IO1, etc.

The first byte addressed can be at any memory location. The address is automatically incremented after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FRQO instruction. FRQO instruction is terminated by driving CE# high (VIH).

If a FRQO instruction is issued while an Erase, Program or Write cycle is in process (BUSY=1) the instruction is ignored and will not have any effects on the current cycle.

Figure 8.7 Fast Read Quad Output Sequence (6Bh)

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

8.9 FAST READ QUAD I/O OPERATION (FRQIO, EBh)

The FRQIO instruction allows the address bits to be input four bits at a time. A Quad Enable (QE) bit of status Register must be set to “1” before sending FRQIO instruction.

The FRQIO instruction code is followed by three address bytes (A23 – A0) and dummy cycles (configurable, default is 6 clocks), transmitted via the IO3, IO2, IO1 and IO0 lines, with each group of four bits latched-in during the rising edge of SCK. The address of MSB inputs on IO3, the next bit on IO2, the next bit on IO1, the next bit on IO0, and continue to shift in alternating on the four. Depending on the usage of AX read operation mode, a mode byte may be located after address input.

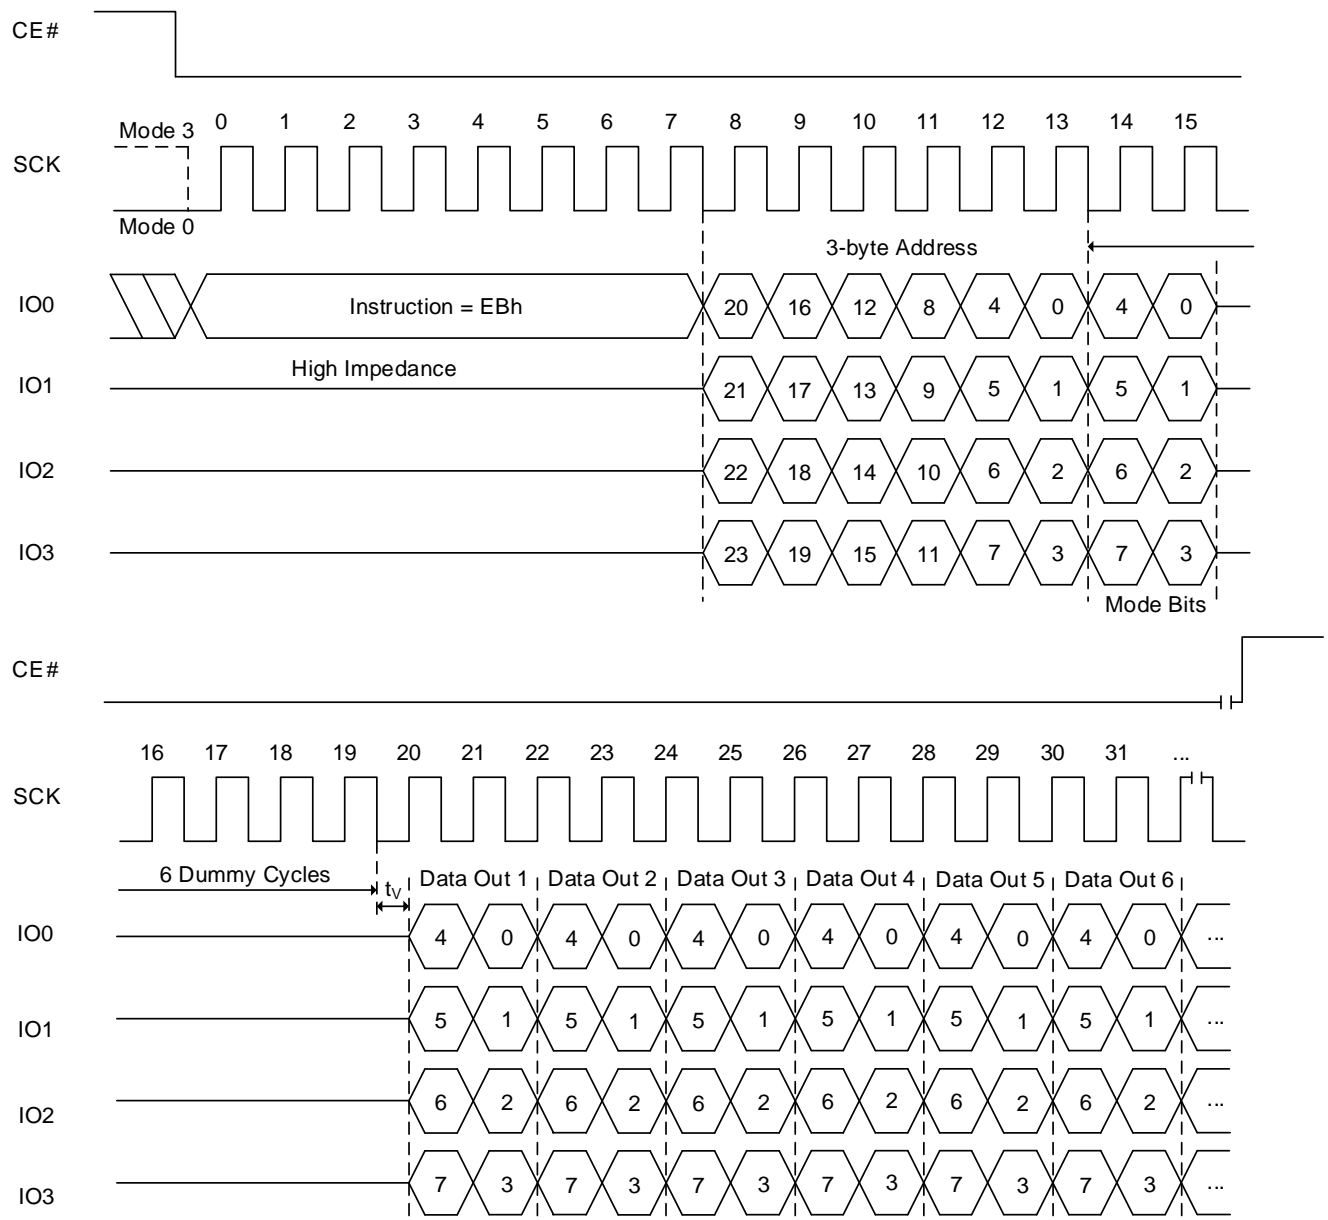

The first data byte addressed is shifted out on the IO3, IO2, IO1 and IO0 lines, with each group of four bits shifted out at a maximum frequency f_{CT} , during the falling edge of SCK. The first bit (MSB) is output on IO3, while simultaneously the second bit is output on IO2, the third bit is output on IO1, etc. Figure 8.8 illustrates the timing sequence.

The first byte addressed can be at any memory location. The address is automatically incremented after each byte of data is shifted out. When the highest address is reached, the address counter will roll over to the 000000h address, allowing the entire memory to be read with a single FRQIO instruction. FRQIO instruction is terminated by driving CE# high (V_{IH}).

The device supports the AX read operation by applying mode bits during dummy period. Mode bits consist of 8 bits, such as M7 to M0. Two cycles after address input are reserved for Mode bits in FRQIO execution. M7 to M4 are important for enabling this mode. M3 to M0 become don't care for future use. When M[7:4]=1010(Ah), it enables the AX read operation and subsequent FRQIO execution skips command code. It saves cycles as described in Figure 8.9. When the code is different from AXh (where X is don't care), the device exits the AX read operation. After finishing the read operation, device becomes ready to receive a new command. SPI or QPI mode configuration retains the prior setting. Mode bit must be applied during dummy cycles. Number of dummy cycles in Table 6.11 includes number of mode bit cycles. If dummy cycles are configured as 6 cycles, data output will start right after mode bits and 4 additional dummy cycles are applied.

If the FRQIO instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not have any effects on the current cycle.

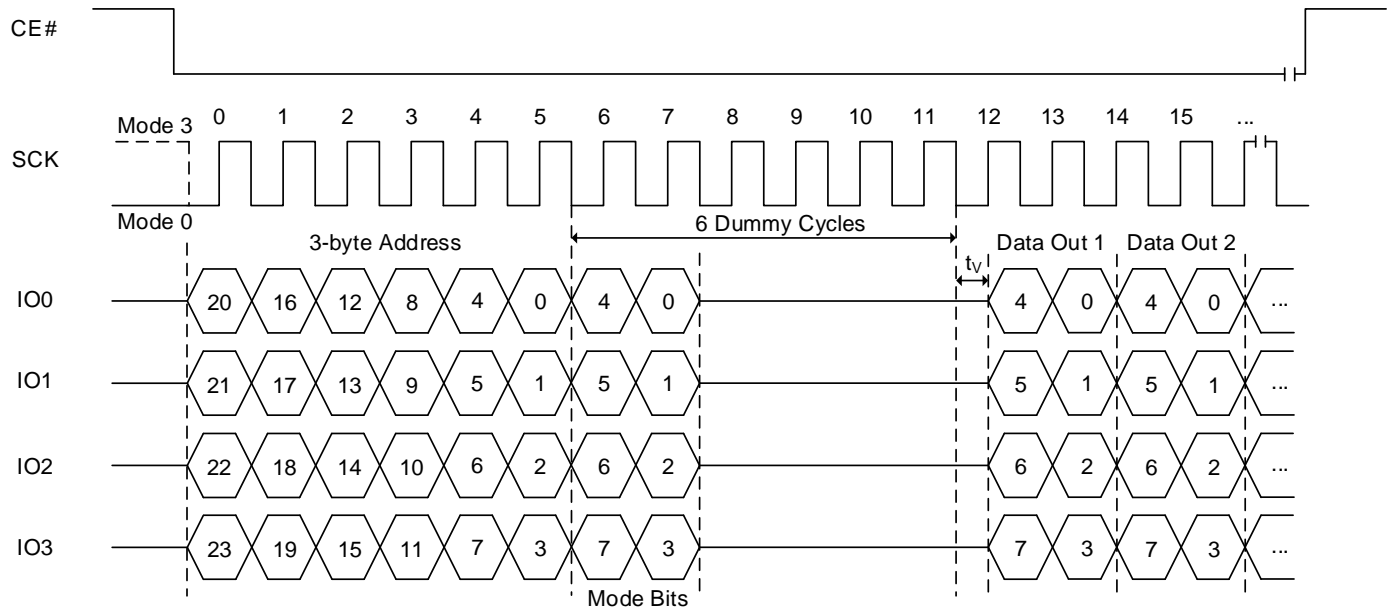

Figure 8.8 Fast Read Quad I/O Sequence (EBh)

Notes:

1. If the mode bits=AXh (where X is don't care), it can execute the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

Figure 8.9 Fast Read Quad I/O AX Read Sequence (EBh)

Notes:

1. If the mode bits=AXh (where X is don't care), it will keep executing the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

8.10 PAGE PROGRAM OPERATION (PP, 02h)

The Page Program (PP) instruction allows up to 256 bytes data to be programmed into memory in a single operation. The destination of the memory to be programmed must be outside the protected memory area set by the Block Protection (BP3, BP2, BP1, BP0) bits. A PP instruction which attempts to program into a page that is write-protected will be ignored. Before the execution of PP instruction, the Write Enable Latch (WEL) must be enabled through a Write Enable (WREN) instruction.

The PP instruction code, three address bytes and program data (1 to 256 bytes) are input via the SI line. Program operation will start immediately after the CE# is brought high, otherwise the PP instruction will not be executed. The internal control logic automatically handles the programming voltages and timing. The progress or completion of the program operation can be determined by reading the WIP bit in Status Register via a RDSR instruction. If the WIP bit is "1", the program operation is still in progress. If WIP bit is "0", the program operation has completed.

If more than 256 bytes data are sent to a device, the address counter rolls over within the same page, the previously latched data are discarded, and the last 256 bytes are kept to be programmed into the page. The starting byte can be anywhere within the page. When the end of the page is reached, the address will wrap around to the beginning of the same page. If the data to be programmed are less than a full page, the data of all other bytes on the same page will remain unchanged.

Note: A program operation can alter "1"s into "0"s. The same byte location or page may be programmed more than once, to incrementally change "1"s to "0"s. An erase operation is required to change "0"s to "1"s.

Figure 8.10 Page Program Sequence (02h)

Figure 8.11 Page Program Sequence In QPI Mode (02h)

8.11 QUAD INPUT PAGE PROGRAM OPERATION (PPQ, 32h/38h)

The Quad Input Page Program instruction allows up to 256 bytes data to be programmed into memory in a single operation with four pins (IO0, IO1, IO2 and IO3). The destination of the memory to be programmed must be outside the protected memory area set by the Block Protection (BP3, BP2, BP1, BP0) bits. A Quad Input Page Program instruction which attempts to program into a page that is write-protected will be ignored.

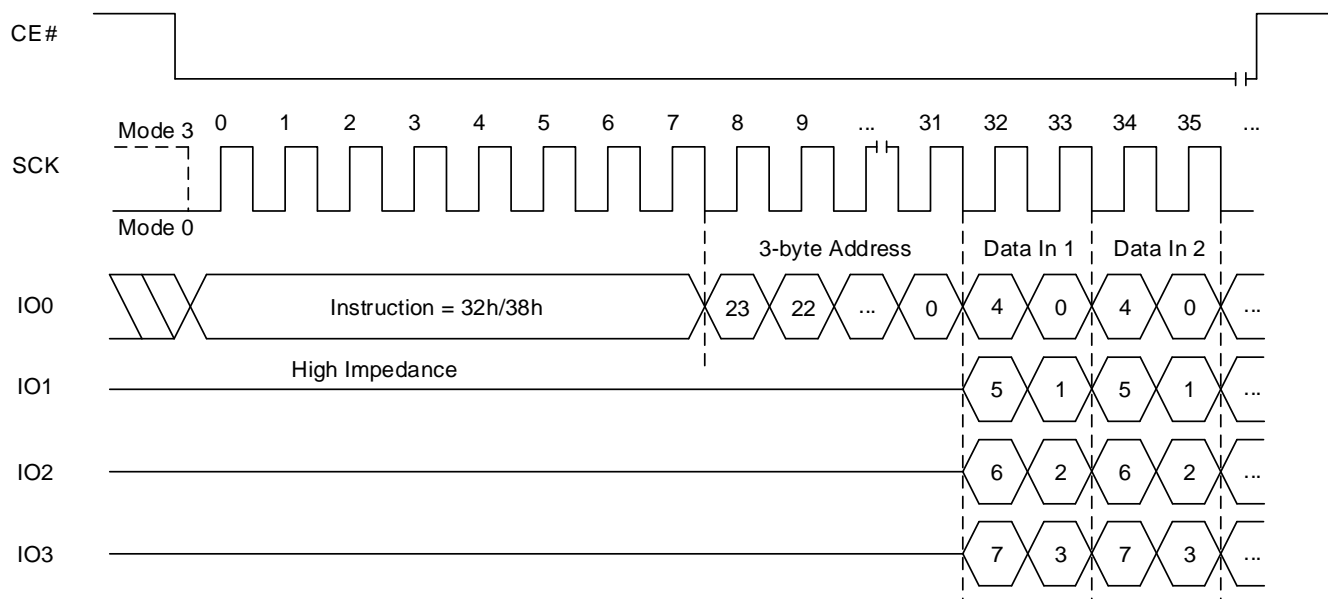

Before the execution of Quad Input Page Program instruction, the QE bit in the Status Register must be set to “1” and the Write Enable Latch (WEL) must be enabled through a Write Enable (WREN) instruction.

After Quad Input Page Program instruction code and three address bytes via IO0, program data (1 to 256 bytes) is transferred via the four pins (IO0, IO1, IO2 and IO3). Program operation will start immediately after the CE# is brought high, otherwise the Quad Input Page Program instruction will not be executed. The internal control logic automatically handles the programming voltages and timing. The progress or completion of the program operation can be determined by reading the WIP bit in Status Register via a RDSR instruction. If the WIP bit is “1”, the program operation is still in progress. If WIP bit is “0”, the program operation has completed.

If more than 256 bytes data are sent to a device, the address counter rolls over within the same page, the previously latched data are discarded, and the last 256 bytes data are kept to be programmed into the page. The starting byte can be anywhere within the page. When the end of the page is reached, the address will wrap around to the beginning of the same page. If the data to be programmed are less than a full page, the data of all other bytes on the same page will remain unchanged.

Note: A program operation can alter “1”s into “0”s. The same byte location or page may be programmed more than once, to incrementally change “1”s to “0”s. An erase operation is required to change “0”s to “1”s.

Figure 8.12 Quad Input Page Program operation (32h/38h)

8.12 ERASE OPERATION

The Erase command sets all bits in the addressed sector or block to “1”s.

The memory array of the device is organized into uniform 4 Kbyte sectors or 32/64 Kbyte uniform blocks (a block consists of eight/sixteen adjacent sectors respectively).

Before a byte is reprogrammed, the sector or block that contains the byte must be erased (erasing sets bits to “1”). In order to erase the device, there are three erase instructions available: Sector Erase (SER), Block Erase (BER), and Chip Erase (CER). A sector erase operation allows any individual sector to be erased without affecting the data in other sectors. A block erase operation erases any individual block. A chip erase operation erases the whole memory array of a device. A sector erase, block erase, or chip erase operation can be executed prior to any programming operation.

8.13 SECTOR ERASE OPERATION (SER, D7h/20h)

A Sector Erase (SER) instruction erases a 4 Kbyte sector before the execution of a SER instruction, the Write Enable Latch (WEL) must be set via a Write Enable (WREN) instruction. The WEL bit is automatically reset after the completion of Sector Erase operation.

A SER instruction is entered, after CE# is pulled low to select the device and stays low during the entire instruction sequence. The SER instruction code, and three address bytes are input via SI. Erase operation will start immediately after CE# is pulled high. The internal control logic automatically handles the erase voltage and timing.

The progress or completion of the erase operation can be determined by reading the WIP bit in the Status Register using a RDSR instruction.

The progress or completion of the erase operation can be determined by reading the WIP bit. If the WIP bit is “1”, the erase operation is still in progress. If the WIP bit is “0”, the erase operation has been completed.

Figure 8.13 Sector Erase Sequence (D7h/20h)

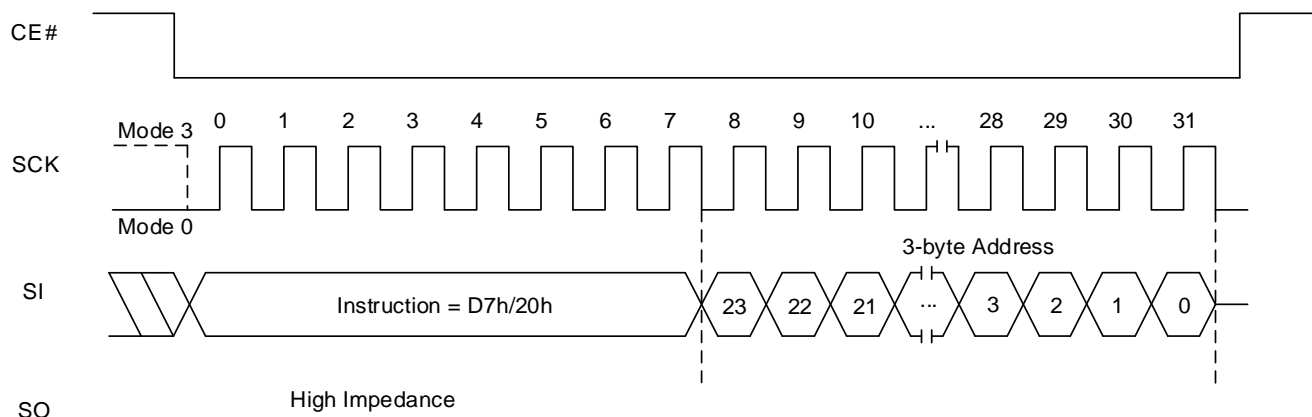

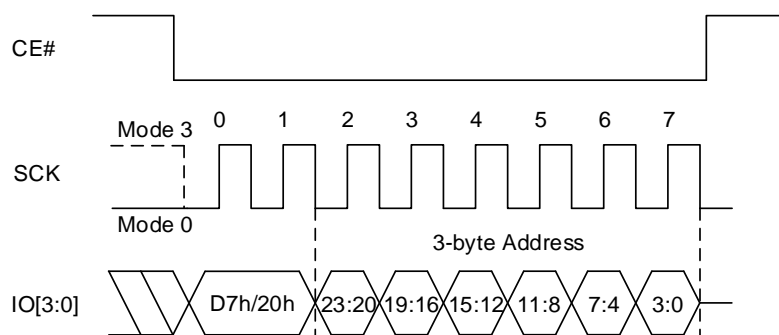

Figure 8.14 Sector Erase Sequence In QPI Mode (D7h/20h)

8.14 BLOCK ERASE OPERATION (BER32K:52h)

A Block Erase (BER) instruction erases a 32/64 Kbyte block. Before the execution of a BER instruction, the Write Enable Latch (WEL) must be set via a Write Enable (WREN) instruction. The WEL is reset automatically after the completion of a block erase operation.

The BER instruction code and three or four address bytes as above are input via SI. Erase operation will start immediately after the CE# is pulled high, otherwise the BER instruction will not be executed. The internal control logic automatically handles the erase voltage and timing.

Figure 8.15 Block Erase (64K) Sequence (D8h)

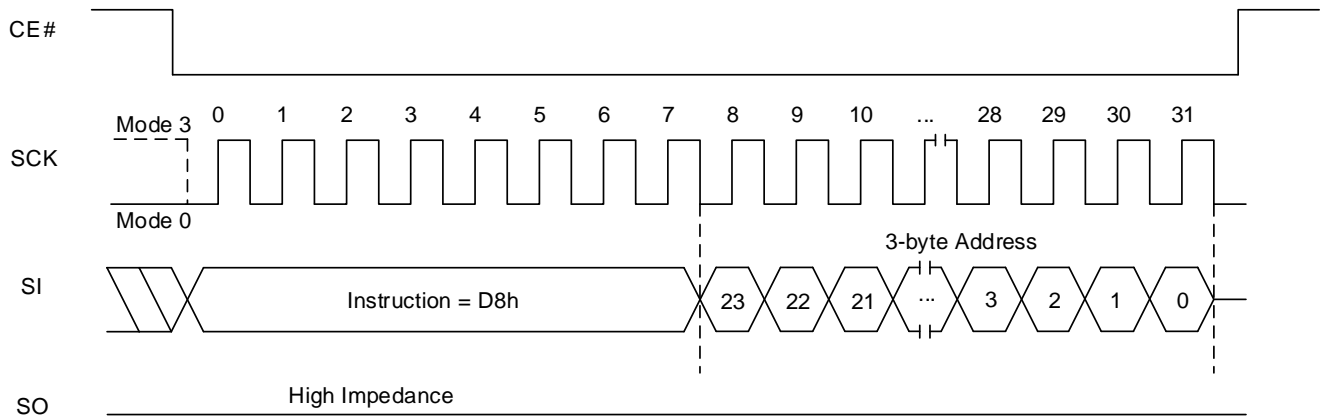

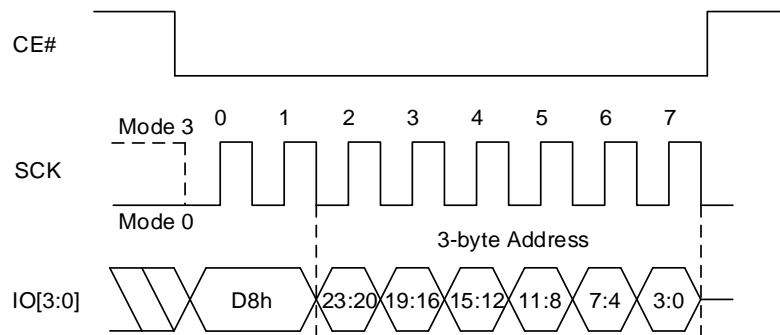

Figure 8.16 Block Erase (64K) Sequence In QPI Mode (D8h)

8.15 CHIP ERASE OPERATION (CER, C7h/60h)

A Chip Erase (CER) instruction erases the entire memory array. Before the execution of CER instruction, the Write Enable Latch (WEL) must be set via a Write Enable (WREN) instruction. The WEL is automatically reset after completion of a chip erase operation.

The CER instruction code is input via the SI. Erase operation will start immediately after CE# is pulled high, otherwise the CER instruction will not be executed. The internal control logic automatically handles the erase voltage and timing.

Chip Erase (CER) instruction can be executed only when Block Protection (BP3~BP0) bits are set to 0s. If the BP bits are not 0, the CER command is not executed and E_ERR and PROT_E are set.

Chip Erase (CER) instruction will skip sectors/blocks protected by ASP (DYB bits or PPB bits) and will **not** set E_ERR and PROT_E if sectors/blocks are protected by ASP only.

Figure 8.17 Chip Erase Sequence In SPI Mode

Figure 8.18 Chip Erase Sequence In QPI Mode

8.16 WRITE ENABLE OPERATION (WREN, 06h)

The Write Enable (WREN) instruction is used to set the Write Enable Latch (WEL) bit. The WEL bit is reset to the write-protected state after power-up. The WEL bit must be write enabled before any write operation, including Sector Erase, Block Erase, Chip Erase, Page Program, Program Information Row, Write Status Register, Write Function Register, Set Non-Volatile Read Register, Set Non-Volatile Extended Read Register, and Write Autoboot Register operations, Set Volatile Read Register and Set Volatile Extended Read Register. The WEL bit will be reset to the write-protected state automatically upon completion of a write operation. The WREN instruction is required before any above operation is executed.

Figure 8.19 Write Enable Sequence In SPI Mode

Figure 8.20 Write Enable Sequence In QPI Mode

8.17 WRITE DISABLE OPERATION (WRDI, 04h)

The Write Disable (WRDI) instruction resets the WEL bit and disables all write instructions. The WRDI instruction is not required after the execution of a write instruction, since the WEL bit is automatically reset.

Figure 8.21 Write Disable Sequence In SPI Mode

Figure 8.22 Write Disable Sequence In QPI Mode

8.18 READ STATUS REGISTER OPERATION (RDSR, 05h)

The Read Status Register (RDSR) instruction provides access to Status Register. During the execution of a program, erase or Write Status Register operation, the RDSR instruction will be executed, which can be used to check the progress or completion of an operation by reading the WIP bit.

Figure 8.23 Read Status Register Sequence In SPI Mode

Figure 8.24 Read Status Register Sequence In QPI Mode

8.19 WRITE STATUS REGISTER OPERATION (WRSR, 01h)

The Write Status Register (WRSR) instruction allows the user to enable or disable the block protection and Status Register write protection features by writing “0”s or “1”s into BP3, BP2, BP1, BP0, and SRWD bits. Also WRSR instruction allows the user to disable or enable quad operation by writing “0” or “1” into the QE bit. To write Status Register bits, a standard Write Enable (06h) instruction must previously have been executed for the device to accept Write Status Register (01h) instruction (Status Register bit WEL must equal 1).

Figure 8.25 Write Status Register Sequence In SPI Mode

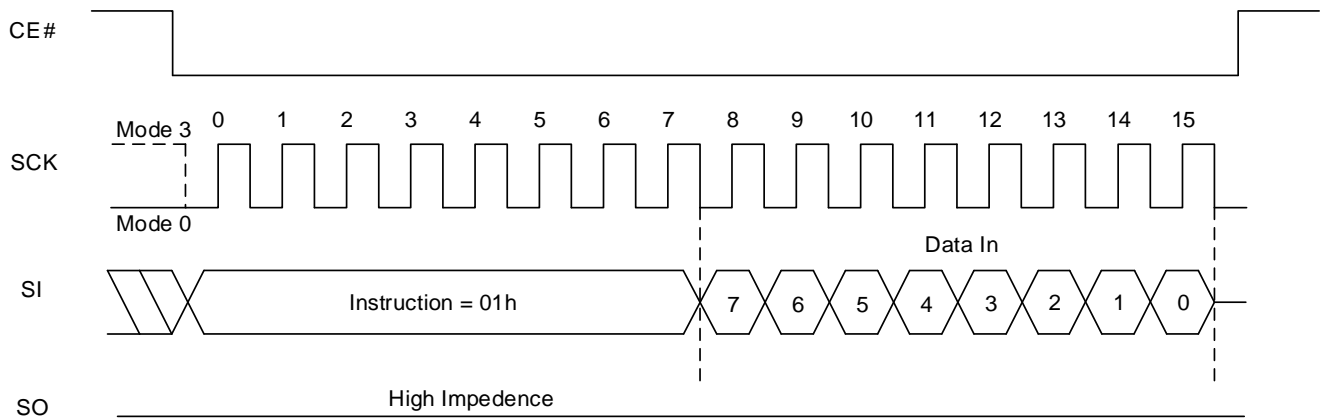

Figure 8.26 Write Status Register Sequence In QPI Mode

8.20 READ FUNCTION REGISTER OPERATION (RDFR, 48h)

The Read Function Register (RDFR) instruction provides access to the Function Register. Refer to Table 6.6 Function Register Bit Definition for more detail.

Figure 8.27 Read Function Register Sequence In SPI Mode

Figure 8.28 Read Function Register Sequence In QPI Mode

8.21 WRITE FUNCTION REGISTER OPERATION (WRFR, 42h)

The Write Function Register (WRFR) instruction allows the user to disable dedicated RESET# pin or ball on 16-pin SOIC or 24 ball TFBGA by setting Dedicated RESET# Disable bit to “1”. Also Information Row Lock bits (IRL3~IRL0) can be set to “1” individually by WRFR instruction in order to lock Information Row. Since Dedicated RESET# Disable bit and IRL bits are OTP, once they are set to “1”, they cannot be set back to “0” again

Figure 8.29 Write Function Register Sequence In SPI Mode

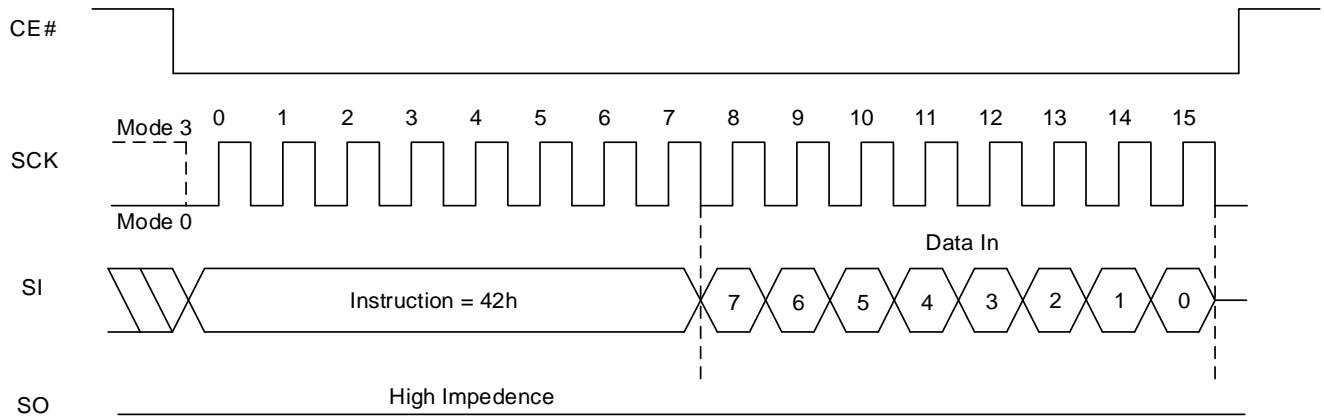

Figure 8.30 Write Function Register Sequence In QPI Mode

8.22 ENTER QUAD PERIPHERAL INTERFACE (QPI) MODE OPERATION (QPIEN, 35h; QPIDI, F5h)

The Enter QPI (QPIEN) instruction, 35h, enables the Flash device for QPI bus operation. Upon completion of the instruction, all instructions thereafter will be 4-bit multiplexed input/output until a power cycle or an Exit QPI instruction is sent to device.

The Exit QPI instruction, F5h, resets the device to 1-bit SPI protocol operation. To execute an Exit QPI operation, the host drives CE# low, sends the Exit QPI command cycle, then drives CE# high. The device just accepts QPI (2 clocks) command cycles.

Figure 8.31 Enter Quad Peripheral Interface (QPI) Mode Sequence

Figure 8.32 Exit Quad Peripheral Interface (QPI) Mode Sequence

8.23 PROGRAM/ERASE SUSPEND & RESUME

The device allows the interruption of Sector Erase, Block Erase, or Page Program operations to conduct other operations. 75h/B0h command for suspend and 7Ah/30h for resume will be used. (SPI/QPI all acceptable) Function Register bit2 (PSUS) and bit3 (ESUS) are used to check whether or not the device is in suspend mode.

Suspend to read ready timing (t_{SUS}): 100 μ s (TYP)
Resume to another suspend timing (t_{RS}): 400 μ s (TYP)

SUSPEND DURING SECTOR-ERASE OR BLOCK-ERASE (PERSUS 75h/B0h)

The Suspend command allows the interruption of Sector Erase and Block Erase operations. But Suspend command will be ignored during Chip Erase operation. After the Suspend command, other commands include array read operation can be accepted.

But Write Status Register command (01h) and Erase instructions are not allowed during Erase Suspend. Also, array read for being erased sector/block is not allowed.

To execute Erase Suspend operation, the host drives CE# low, sends the Suspend command cycle (75h/B0h), then drives CE# high. The Function Register indicates that the Erase has been suspended by setting the ESUS bit from "0" to "1", but the device will not accept another command until it is ready. To determine when the device will accept a new command, poll the WIP bit or wait the specified time t_{SUS} . When ESUS bit is set to "1", the Write Enable Latch (WEL) bit clears to "0".

SUSPEND DURING PAGE PROGRAMMING (PERSUS 75h/B0h)

The Suspend command also allows the interruption of all array Program operations. After the Suspend command, other commands include array read operation can be accepted can be accepted.

But Write Status Register instruction (01h) and Program instructions are not allowed during Program Suspend. Also, array read for being programmed page is not allowed.

To execute the Program Suspend operation, the host drives CE# low, sends the Suspend command cycle (75h/B0h), then drives CE# high. The Function Register indicates that the programming has been suspended by setting the PSUS bit from "0" to "1", but the device will not accept another command until it is ready. To determine when the device will accept a new command, poll the WIP bit or wait the specified time t_{SUS} . When PSUS bit is set to "1", the Write Enable Latch (WEL) bit clears to "0".

PROGRAM/ERASE RESUME (PERRSM 7Ah/30h)

The Program/Erase Resume restarts the Program or Erase command that was suspended, and clears the suspend status bit in the Function Register (ESUS or PSUS bits) to "0". To execute the Program/Erase Resume operation, the host drives CE# low, sends the Program/Erase Resume command cycle (7Ah/30h), then drives CE# high. A cycle is two nibbles long, most significant nibble first. To issue another Erase Suspend operation after Erase Resume operation, Erase Resume to another Erase Suspend delay (400us) is required, but it could require longer Erase time to complete Erase operation.

To determine if the internal, self-timed Write operation completed, poll the WIP bit.

Table 8.3 Instructions accepted during Suspend

Operation Suspend	Instruction Allowed		
	Name	Hex Code	Operation
Program or Erase	NORD	03h	Normal Read Mode
Program or Erase	FRD	0Bh	Fast Read Mode
Program or Erase	FRDIO	BBh	Fast Read Dual I/O
Program or Erase	FRDO	3Bh	Fast Read Dual Output
Program or Erase	FRQIO	EBh	Fast Read Quad I/O
Program or Erase	FRQO	6Bh	Fast Read Quad Output
Program or Erase	FRDTR	0Dh	Fast Read DTR Mode
Program or Erase	FRDDTR	BDh	Fast Read Dual I/O DTR
Program or Erase	FRQDTR	EDh	Fast Read Quad I/O DTR
Program or Erase	WREN	06h	Write Enable
Program or Erase	WRDI	04hh	Write Disable
Program or Erase	RDSR	05h	Read Status Register
Program or Erase	RDFR	48h	Read Function Register
Program or Erase	RDRP	61h	Read Read Parameters (Volatile)
Program or Erase	RDERP	81h	Read Extended Read Parameters (Volatile)
Program or Erase	RDID	ABh	Read Manufacturer and Product ID
Program or Erase	RDJDID	9Fh	Read Manufacturer and Product ID by JEDEC ID Command
Program or Erase	RDMDID	90h	Read Manufacturer and Device ID
Program or Erase	RDJDIDQ	AFh	Read JEDEC ID QPI mode
Program or Erase	RDUID	4Bh	Read Unique ID Number
Program or Erase	RDSFDP	5Ah	SFDP Read
Program or Erase	CLERP	82h	Clear Extended Read Register

Operation Suspended	Instruction Allowed		
	Name	Hex Code	Operation
Program or Erase	PERRSM	7Ah/30h	Program/Erase Resume
Program or Erase	SRPV	C0h/63h	Set Read Parameters (Volatile)
Program or Erase	SERPVS	83h	Set Extended Read Parameters (Volatile)
Program or Erase	RDPPB	FCh	Read PPB
Program or Erase	RDDYB	FAh	Read DYB
Program or Erase	RDPWD	E7h	Read Password
Program or Erase	RDPLB	A7h	Read PPB Lock Bit
Program or Erase	RDASP	2Bh	Read ASP
Erase	SECLOCK	24h	Sector Lock
Erase	SECUNLOCK	26h	Sector Unlock
Erase	PERSUS	75h/B0h	Program/Erase Suspend
Erase	PP	02h	Serial Input Page Program
Erase	PPQ	32h/38h	Quad Input Page Program
Erase	WRDYB	FBh	Write DYB

8.24 ENTER DEEP POWER DOWN (DP, B9h)

The Deep Power-down (DP) instruction is for setting the device on the minimizing the power consumption (enter into Power-down mode). During this mode, standby current is reduced from I_{sb1} to I_{sb2} . While in the Power-down mode, the device is not active and all Write/Program/Erase instructions are ignored. The instruction is initiated by driving the CE# pin low and shifting the instruction code into the device. The CE# pin must be driven high after the instruction has been latched, or Power-down mode will not engage. Once CE# pin driven high, the Power-down mode will be entered within the time duration of t_{DP} . While in the Power-down mode only the Release from Power-down/RDID instruction, which restores the device to normal operation, will be recognized. All other instructions are ignored, including the Read Status Register instruction which is always available during normal operation. Ignoring all but one instruction makes the Power Down state a useful condition for securing maximum write protection. It is available in both SPI and QPI mode.

Figure 8.33 Enter Deep Power Down Mode Sequence

Figure 8.34 Enter Deep Power Down Mode QPI Sequence

8.25 RELEASE DEEP POWER DOWN (RDPD, ABh)

The Release Deep Power-down/Read Device ID instruction is a multi-purpose command. To release the device from the deep power-down mode, the instruction is issued by driving the CE# pin low, shifting the instruction code into the device and driving CE# high.

Releasing the device from Power-down mode will take the time duration of t_{RES1} before normal operation is restored and other instructions are accepted. The CE# pin must remain high during the t_{RES1} time duration. If the Release Deep Power-down/RDID instruction is issued while an Erase, Program or Write cycle is in progress (WIP=1) the instruction is ignored and will not have any effects on the current cycle.

Figure 8.35 Release Power Down Mode Sequence In SPI Mode

Figure 8.36 Release Power Down Mode Sequence In QPI Mode

8.26 SET READ PARAMETERS OPERATION (SRPNV: 65h, SRPV: C0h/63h)

Set Read Parameter Bits

This device supports configurable burst length and dummy cycles in both SPI and QPI mode by setting three bits (P2, P1, P0) and four bits (P6, P5, P4, P3) within the Read Register, respectively. To set those bits the SRPNV and SRPV operation instruction are used. Details regarding burst length and dummy cycles can be found in Table 6.9, Table 6.10, and Table 6.11. HOLD#/RESET# function selection (P7) bit in the Read Register can be set with the SRPNV and SRPV operation as well, in order to select HOLD#/RESET# pin as RESET# or HOLD#.

For the device with dedicated RESET# pin (or ball), RESET# pin (or ball) will be a separate pin (or ball) and it is independent of the P7 bit setting in Read Register.

SRPNV is used to set the non-volatile Read Register, while SRPV is used to set the volatile Read Register.

To write non-volatile Read Parameter bits, a standard Write Enable (06h) instruction must previously have been executed for the device to accept SRPNV(65h) instruction (Status Register bit WEL must equal "1").

To write volatile Read Parameter bits (SRPV), 63h or C0h command can be used.

When using 63h instruction, a standard Write Enable (06h) instruction must previously have been executed for the device to accept SRPV (63h) instruction (Status Register bit WEL must equal "1").

But C0h instruction does not require a standard Write Enable (06h) operation. (Status Register bit WEL remains "0").

Note: When SRPNV is executed, the volatile Read Register is set as well as the non-volatile Read Register.

Figure 8.37 Set Read Parameters Sequence In SPI Mode

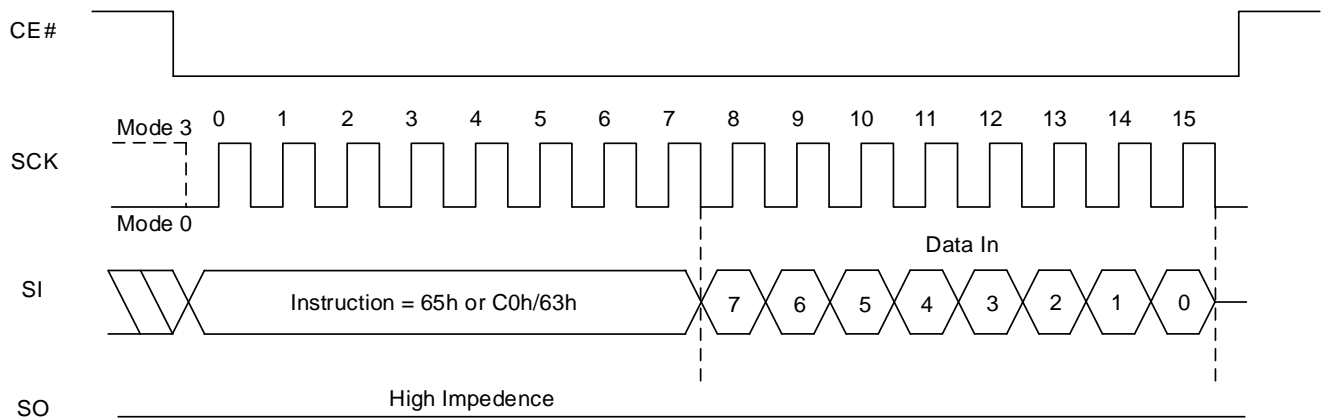

Figure 8.38 Set Read Parameters Sequence In QPI Mode

Read with “8/16/32/64-Byte Wrap Around”

The device is capable of burst read with wrap around in both SPI and QPI mode. The size of burst length is configurable by using P0, P1, and P2 bits in Read Register. P2 bit (Wrap enable) enables the burst mode feature. P0 and P1 define the size of burst. Burst lengths of 8, 16, 32, and 64 bytes are supported. By default, address increases by one up through the entire array. By setting the burst length, the data being accessed can be limited to the length of burst boundary within a 256 byte page. The first output will be the data at the initial address which is specified in the instruction. Following data will come out from the next address within the burst boundary. Once the address reaches the end of boundary, it will automatically move to the first address of the boundary. CE# high will terminate the command.

For example, if burst length of 8 and initial address being applied is 0h, following byte output will be from address 00h and continue to 01h,...,07h, 00h, 01h... until CE# terminates the operation. If burst length of 8 and initial address being applied is FEh(254d), following byte output will be from address FEh and continue to FFh, F8h, F9h, FAh, FBh, FCh, FDh, and repeat from FEh until CE# terminates the operation.

The commands, “SRPV (65h) or SRPNV (C0h or 63h)”, are used to configure the burst length. If the following data input is one of “00h”, “01h”, “02h”, and “03h”, the device will be in default operation mode. It will be continuous burst read of the whole array. If the following data input is one of “04h”, “05h”, “06h”, and “07h”, the device will set the burst length as 8, 16, 32 and 64, respectively.

To exit the burst mode, another “C0h or 63h” command is necessary to set P2 to 0. Otherwise, the burst mode will be retained until either power down or reset operation. To change burst length, another “C0h or 63h” command should be executed to set P0 and P1 (Detailed information in Table 6.9 Burst Length Data). All read commands will operate in burst mode once the Read Register is set to enable burst mode.

Refer to Figure 8.59 and Figure 8.60 for instruction sequence.

8.27 SET EXTENDED READ PARAMETERS OPERATION (SERPNV: 85h, SERPV: 83h)
Set Read Operational Driver Strength

This device supports configurable Operational Driver Strength in both SPI and QPI modes by setting three bits (ODS0, ODS1, ODS2) within the Extended Read Register. To set the ODS bits the SERPNV and SERPV operation instructions are required. The device's driver strength can be reduced as low as 12.50% of full drive strength. Details regarding the driver strength can be found in Table 6.14.

SERPNV is used to set the non-volatile Extended Read register, while SERPV is used to set the volatile Extended Read register.

Notes:

1. The default driver strength is set to 50%.
2. When SERPNV is executed, the volatile Read Extended Register is set as well as the non-volatile Read Extended Register.

Figure 8.39 Set Extended Read Parameters Sequence In SPI Mode

Figure 8.40 Set Extended Read Parameters Sequence In QPI Mode

8.28 READ READ PARAMETERS OPERATION (RDRP, 61h)

Prior to, or after setting Read Register, the data of the Read Register can be confirmed by the RDRP command. The instruction is only applicable for the volatile Read Register, not for the non-volatile Read Register.

Figure 8.41 Read Read Parameters Sequence In SPI Mode

Figure 8.42 Read Read Parameters Sequence In QPI Mode

8.29 READ EXTENDED READ PARAMETERS OPERATION (RDERP, 81h)

Prior to, or after setting Extended Read Register, the data of the Extended Read Register can be confirmed by the RDERP command. The instruction is only applicable for the volatile Extended Read Register, not for the non-volatile Extended Read Register.

During the execution of a Program, Erase or Write Non-Volatile Register operation, the RDERP instruction will be executed, which can be used to check the progress or completion of an operation by reading the WIP bit.

Figure 8.43 Read Extended Read Parameters Sequence In SPI Mode

Figure 8.44 Read Extended Read Parameters Sequence In QPI Mode

8.30 CLEAR EXTENDED READ REGISTER OPERATION (CLERP, 82h)

A Clear Extended Read Register (CLERP) instruction clears PROT_E, P_ERR, and E_ERR error bits in the Extended Read Register to “0” when the error bits are set to “1”. Once the error bits are set to “1”, they remain set to “1” until they are cleared to “0” with a CLERP command.

Figure 8.45 Clear Extended Read Register Sequence In SPI Mode

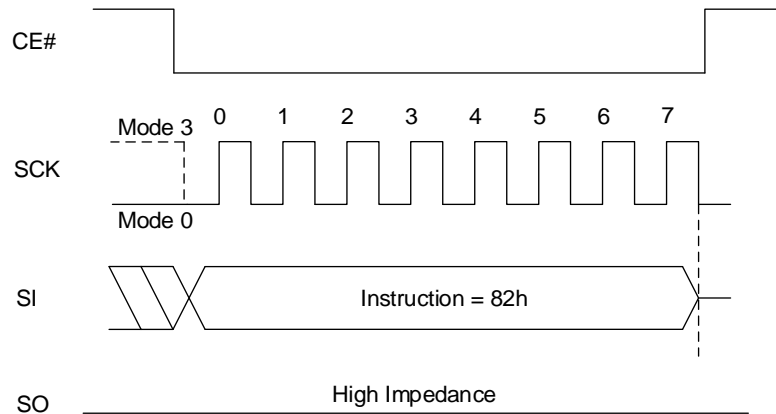

Figure 8.46 Clear Extended Read Register Sequence In QPI Mode

8.31 READ PRODUCT IDENTIFICATION (RDID, ABh)

The Release from Power-down/Read Device ID instruction is a multi-purpose instruction. It can support both SPI and QPI modes. The Read Product Identification (RDID) instruction is for reading out the old style of 8-bit Electronic Signature, whose values are shown as the table of Product Identification.

The RDID instruction code is followed by three dummy bytes, each bit being latched-in on SI during the rising SCK edge. Then the Device ID is shifted out on SO with the MSB first, each bit been shifted out during the falling edge of SCK. The RDID instruction is ended by driving CE# high. The Device ID (ID7-ID0) outputs repeatedly if additional clock cycles are continuously sent to SCK while CE# is at low.

Table 8.4 Product Identification

Manufacturer ID		(MF7-MF0)	
ISSI Serial Flash		9Dh	
Instruction	ABh	90h	9Fh
Part Number	Device ID (ID7-ID0)		Memory Type + Capacity (ID15-ID0)
IS25LP064D	16h		6017h
IS25WP064D	16h		7017h

Figure 8.47 Read Product Identification Sequence

Figure 8.48 Read Product Identification Sequence In QPI Mode

8.32 READ PRODUCT IDENTIFICATION BY JEDEC ID OPERATION (RDJDID, 9Fh; RDJDIDQ, AFh)

The JEDEC ID READ instruction allows the user to read the manufacturer and product ID of devices. Refer to Table 8.7 Product Identification for Manufacturer ID and Device ID. After the JEDEC ID READ command (9Fh in SPI mode, AFh in QPI mode) is input, the Manufacturer ID is shifted out MSB first followed by the 2-byte electronic ID (ID15-ID0) that indicates Memory Type and Capacity, one bit at a time. Each bit is shifted out during the falling edge of SCK. If CE# stays low after the last bit of the 2-byte electronic ID, the Manufacturer ID and 2-byte electronic ID will loop until CE# is pulled high.

Figure 8.49 Read Product Identification by JEDEC ID Read Sequence In SPI Mode

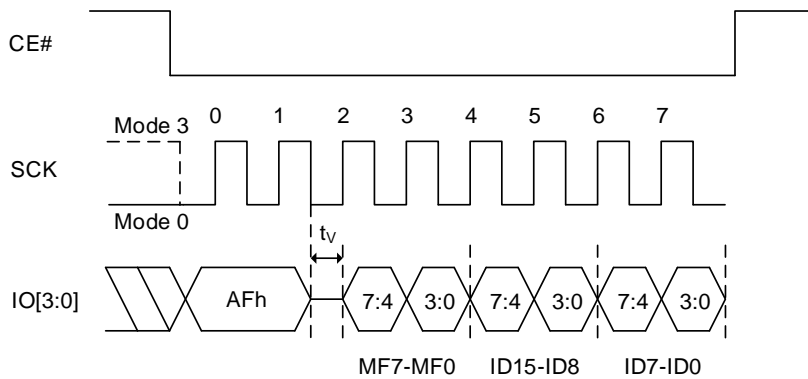

Figure 8.50 RDJDID and RDJDIDQ (Read JEDEC ID) Sequence In QPI Mode

8.33 READ DEVICE MANUFACTURER AND DEVICE ID OPERATION (RDMDID, 90h)

The Read Device Manufacturer and Device ID (RDMDID) instruction allows the user to read the Manufacturer and product ID of devices. Refer to Table 8.7 Product Identification for Manufacturer ID and Device ID. The RDMDID instruction code is followed by two dummy bytes and one byte address (A7~A0), each bit being latched-in on SI during the rising edge of SCK. If one byte address is initially set as A0 = 0, then the Manufacturer ID is shifted out on SO with the MSB first followed by the device ID (ID7- ID0). Each bit is shifted out during the falling edge of SCK. If one byte address is initially set as A0 = 1, then Device ID7-ID0 will be read first followed by the Manufacturer ID. The Manufacturer and Device ID can be read continuously alternating between the two until CE# is driven high.

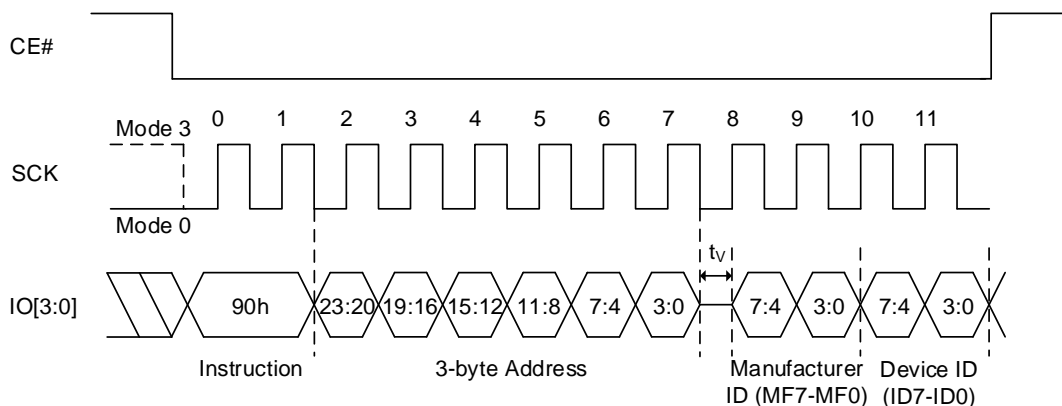

Figure 8.51 Read Product Identification by RDMDID Sequence In SPI Mode

Notes:

1. ADDRESS A0 = 0, will output the 1-byte Manufacturer ID (MF7-MF0) → 1-byte Device ID (ID7-ID0)
 ADDRESS A0 = 1, will output the 1-byte Device ID (ID7-ID0) → 1-byte Manufacturer ID (MF7-MF0)
2. The Manufacturer and Device ID can be read continuously and will alternate from one to the other until CE# pin is pulled high.

Figure 8.52 Read Product Identification by RDMDID Sequence In QPI Mode

Notes:

1. ADDRESS A0 = 0, will output the 1-byte Manufacturer ID (MF7-MF0) → 1-byte Device ID (ID7-ID0)
 ADDRESS A0 = 1, will output the 1-byte Device ID (ID7-ID0) → 1-byte Manufacturer ID (MF7-MF0)
2. The Manufacturer and Device ID can be read continuously and will alternate from one to the other until CE# pin is pulled high.

8.34 READ UNIQUE ID NUMBER (RDUID, 4Bh)

The Read Unique ID Number (RDUID) instruction accesses a factory-set read-only 16-byte number that is unique to the device. The ID number can be used in conjunction with user software methods to help prevent copying or cloning of a system. The RDUID instruction is instated by driving the CE# pin low and shifting the instruction code (4Bh) followed by 3 address bytes and dummy cycles (configurable, default is 8 clocks). After which, the 16-byte ID is shifted out on the falling edge of SCK as shown below.

As a result, the sequence of RDUID instruction is same as FAST READ. RDUID sequence in QPI mode is also same as FAST READ sequence in QPI mode except for the instruction code. Refer to the FAST READ operation in QPI mode.

Note: 16 bytes of data will repeat as long as CE# is low and SCK is toggling.

Figure 8.53 RDUID Sequence In SPI Mode

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

Table 8.5 Unique ID Addressing

A[23:16]	A[15:9]	A[8:4]	A[3:0]
XXh	XXh	00h	0h Byte address
XXh	XXh	00h	1h Byte address
XXh	XXh	00h	2h Byte address
XXh	XXh	00h	⋮
XXh	XXh	00h	Fh Byte address

Note: XX means “don’t care”.

8.35 READ SFDP OPERATION (RDSFDP, 5Ah)

The Serial Flash Discoverable Parameters (SFDP) standard provides a consistent method of describing the functions and features of serial Flash devices in a standard set of internal parameter tables. These parameters can be interrogated by host system software to enable adjustments needed to accommodate divergent features from multiple vendors. For more details please refer to the JEDEC Standard JESD216 (Serial Flash Discoverable Parameters).

The sequence of issuing RDSFDP instruction in SPI mode is:

CE# goes low → Send RDSFDP instruction (5Ah) → Send 3 address bytes on SI pin → Read SFDP code on SO after dummy cycles (default 8 cycles) → End RDSFDP operation by driving CE# high at any time during data out.

Figure 8.54 RDSFDP (Read SFDP) Sequence

8.36 NO OPERATION (NOP, 00h)

The No Operation command solely cancels a Reset Enable command and has no impact on any other commands. It is available in both SPI and QPI modes. To execute a NOP, the host drives CE# low, sends the NOP command cycle (00H), then drives CE# high.

8.37 SOFTWARE RESET (RESET-ENABLE (RSTEN, 66h) AND RESET (RST, 99h) AND HARDWARE RESET

The Software Reset operation is used as a system reset that puts the device in normal operating mode. During the Reset operation, the value of volatile registers will default back to the value in the corresponding non-volatile register. However, the volatile FREEZE bit and the volatile PPB Lock bit in the PPB Lock Register are not changed by Software Reset. In all other respects, Software Reset is the same as Hardware Reset. This operation consists of two commands: Reset-Enable (RSTEN) and Reset (RST). The operation requires the Reset-Enable command followed by the Reset command. Any command other than the Reset command after the Reset-Enable command will disable the Reset-Enable.

Execute the CE# pin low → sends the Reset-Enable command (66h), and drives CE# high. Next, the host drives CE# low again, sends the Reset command (99h), and pulls CE# high.

Only if the RESET# pin is enabled, Hardware Reset function is available.

For the device with HOLD#/RESET#, the RESET# pin will be solely applicable in SPI mode and when the QE bit = "0". For the device with dedicated RESET# (Dedicated RESET# Disable bit is "0" in Function Register), the RESET# pin is always applicable regardless of the QE bit value in Status Register and HOLD#/RESET# selection bit (P7) in Read Register in SPI/QPI mode.

In order to activate Hardware Reset, the RESET# pin (or ball) must be driven low for a minimum period of t_{RESET} (100ns). Drive RESET# low for a minimum period of t_{RESET} will interrupt any on-going internal and external operations, release the device from deep power down mode¹, disable all input signals, force the output pin enter a state of high impedance, and reset all the read parameters.

The required wait time after activating a HW Reset before the device will accept another instruction is t_{HWRST} of 35us.

The Software/Hardware Reset during an active Program or Erase operation aborts the operation, which can result in corrupting or losing the data of the targeted address range. Depending on the prior operation, the reset timing may vary. Recovery from a Write operation will require more latency than recovery from other operations.

Note1: The Status and Function Registers remain unaffected.

Figure 8.55 Software Reset Enable and Software Reset Sequence (RSTEN, 66h + RST, 99h)

Figure 8.56 Software Reset Enable and Software Reset QPI Sequence (RSTEN, 66h + RST, 99h)

8.38 SECURITY INFORMATION ROW

The security Information Row is comprised of an additional 4 x 256 bytes of programmable information. The security bits can be reprogrammed by the user. Any program security instruction issued while an erase, program or write cycle is in progress is rejected without having any effect on the cycle that is in progress.

Table 8.6 Information Row Valid Address Range

Address Assignment	A[23:16]	A[15:8]	A[7:0]
IRL0 (Information Row Lock0)	00h	00h	Byte address
IRL1	00h	10h	Byte address
IRL2	00h	20h	Byte address
IRL3	00h	30h	Byte address

Bit 7~4 of the Function Register is used to permanently lock the programmable memory array.

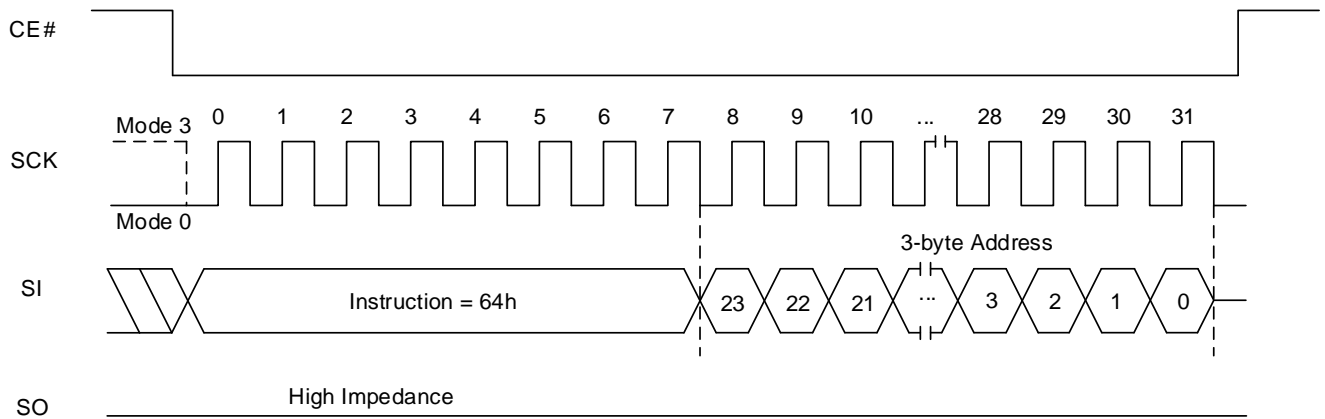

When Function Register bit IRLx = "0", the 256 bytes of the programmable memory array can be programmed. When Function Register bit IRLx = "1", the 256 bytes of the programmable memory array function as read only.

8.39 INFORMATION ROW ERASE OPERATION (IRER, 64h)

Information Row Erase (IRER) instruction erases the data in the Information Row x (x: 0~3) array. Prior to the operation, the Write Enable Latch (WEL) must be set via a Write Enable (WREN) instruction. The WEL bit is automatically reset after the completion of the operation.

The sequence of IRER operation: Pull CE# low to select the device → Send IRER instruction code → Send three address bytes → Pull CE# high. CE# should remain low during the entire instruction sequence. Once CE# is pulled high, Erase operation will begin immediately. The internal control logic automatically handles the erase voltage and timing.

Figure 8.57 IRER (Information Row Erase) Sequence

8.40 INFORMATION ROW PROGRAM OPERATION (IRP, 62h)

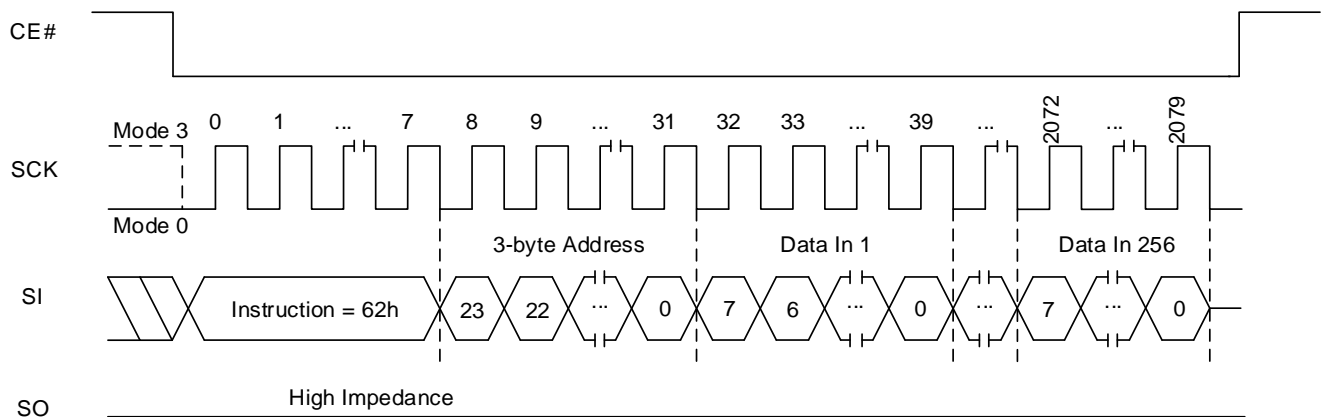

The Information Row Program (IRP) instruction allows up to 256 bytes data to be programmed into the memory in a single operation. Before the execution of IRP instruction, the Write Enable Latch (WEL) must be enabled through a Write Enable (WREN) instruction.

The IRP instruction code, three address bytes and program data (1 to 256 bytes) should be sequentially input. Three address bytes has to be input as specified in the Table 8.9 Information Row Valid Address Range. Program operation will start once the CE# goes high, otherwise the IRP instruction will not be executed. The internal control logic automatically handles the programming voltages and timing. During a program operation, all instructions will be ignored except the RDSR instruction. The progress or completion of the program operation can be determined by reading the WIP bit. If the WIP bit is “1”, the program operation is still in progress. If WIP bit is “0”, the program operation has completed.

If more than 256 bytes data are sent to a device, the address counter rolls over within the same page. The previously latched data are discarded and the last 256 bytes data are kept to be programmed into the page. The starting byte can be anywhere within the page. When the end of the page is reached, the address will wrap around to the beginning of the same page. If the data to be programmed are less than a full page, the data of all other bytes on the same page will remain unchanged.

Note: A program operation can alter “1”s into “0”s, but an erase operation is required to change “0”s back to “1”s. A byte cannot be reprogrammed without first erasing the corresponding Information Row array which is one of IR0~3.

Figure 8.58 IRP (Information Row Program) Sequence

8.41 INFORMATION ROW READ OPERATION (IRRD, 68h)

The IRRD instruction is used to read memory data.

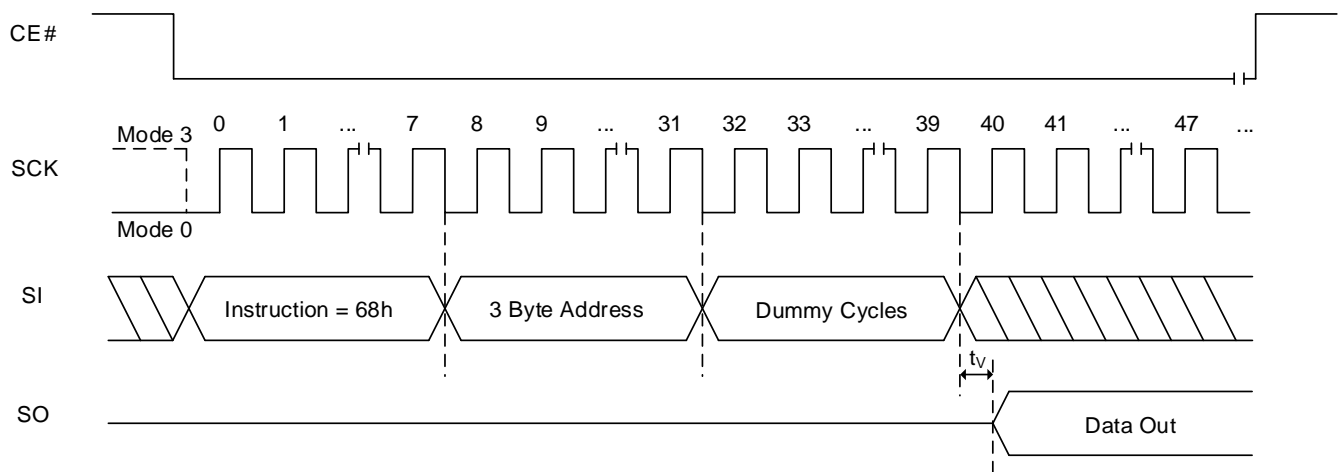

The IRRD instruction code is followed by three address bytes (A23 - A0) and dummy cycles (configurable, default is 8 clocks), transmitted via the SI line, with each bit latched-in during the rising edge of SCK. Then the first data byte addressed is shifted out on the SO line, with each bit shifted out at a maximum frequency f_{CT} , during the falling edge of SCK.

The address is automatically incremented by one after each byte of data is shifted out. Once the address reaches the last address of each 256 byte Information Row, the next address will not be valid and the data of the address will be garbage data. It is recommended to repeat four times IRRD operation that reads 256 byte with a valid starting address of each Information Row in order to read all data in the 4 x 256 byte Information Row array. The IRRD instruction is terminated by driving CE# high (VIH).

If an IRRD instruction is issued while an Erase, Program or Write cycle is in process (WIP=1) the instruction is ignored and will not have any effects on the current cycle

The sequence of IRRD instruction is same as Fast Read except for the instruction code. IRRD QPI sequence is same as Fast Read QPI except for the instruction code. Refer to the Fast Read QPI operation.

Figure 8.59 IRRD (Information Row Read) Sequence

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

8.42 FAST READ DTR MODE OPERATION (FRDTR, 0Dh)

The FRDTR instruction is for doubling the data in and out. Signals are triggered on both rising and falling edge of clock. The address is latched on both rising and falling edge of SCK, and data of each bit shifts out on both rising and falling edge of SCK. The 2-bit address can be latched-in at one clock, and 2-bit data can be read out at one clock, which means one bit at the rising edge of clock, the other bit at the falling edge of clock.

The first address byte can be at any location. The address is automatically increased to the next higher address after each byte of data is shifted out, so the whole memory can be read out in a single FRDTR instruction. The address counter rolls over to 0 when the highest address is reached.

The sequence of issuing FRDTR instruction is: CE# goes low → Sending FRDTR instruction code (1bit per clock) → 3-byte on SI (2-bit per clock) as above → 8 dummy clocks (configurable, default is 8 clocks) on SI → Data out on SO (2-bit per clock) → End FRDTR operation via driving CE# high at any time during data out.

While a Program/Erase/Write Status Register cycle is in progress, FRDTR instruction will be rejected without any effect on the current cycle.

Figure 8.60 FRDTR Sequence (0Dh)

Note: Dummy cycles depends on Read Parameter setting. Detailed information in Table 6.11 Read Dummy Cycles.

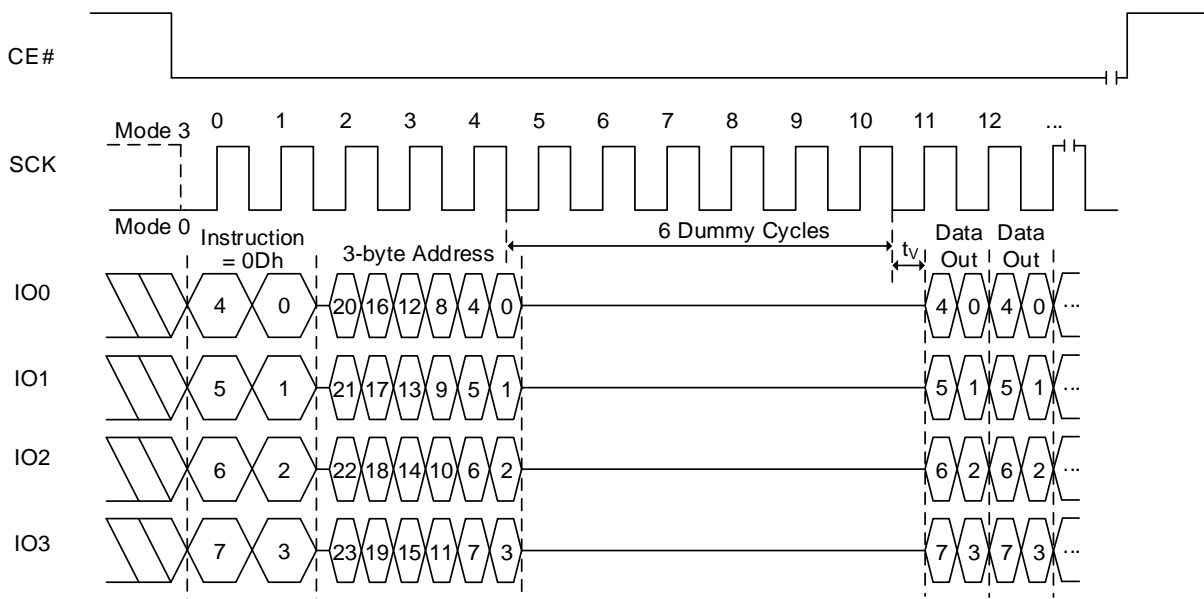

FAST READ DTR MODE OPERATION IN QPI MODE (FRDTR, 0Dh)

The FRDTR instruction in QPI mode utilizes all four IO lines to input the instruction code so that only two clocks are required, while the FRDTR instruction in SPI mode requires that the byte-long instruction code is shifted into the device only via IO0 (SI) line in eight clocks. In addition, subsequent address and data out are shifted in/out via all four IO lines unlike the FRDTR instruction. Eventually this operation is same as the FRQDTR in QPI mode, but the only different thing is that AX mode is not available in the FRDTR operation in QPI mode.

The sequence of issuing FRDTR QPI instruction is: CE# goes low → Sending FRDTR QPI instruction (4-bit per clock) → 24-bit interleave on IO3, IO2, IO1 & IO0 (8-bit per clock) as above → 6 dummy clocks (configurable, default is 6 clocks) → Data out interleave on IO3, IO2, IO1 & IO0 (8-bit per clock) → End FRDTR QPI operation by driving CE# high at any time during data out.

If the FRDTR instruction in QPI mode is issued while an Erase, Program or Write cycle is in process is in progress (WIP=1), the instruction will be rejected without any effect on the current cycle.

Figure 8.61 FRDTR Sequence In QPI Mode (0Dh)

Notes:

1. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
2. Sufficient dummy cycles are required to avoid I/O contention.

8.43 FAST READ DUAL IO DTR MODE OPERATION (FRDDTR, BDh)

The FRDDTR instruction enables Double Transfer Rate throughput on dual I/O of the device in read mode. The address (interleave on dual I/O pins) is latched on both rising and falling edge of SCK, and the data (interleave on dual I/O pins) shift out on both rising and falling edge of SCK. The 4-bit address can be latched-in at one clock, and 4-bit data can be read out at one clock, which means two bits at the rising edge of clock, the other two bits at the falling edge of clock.

The first address byte can be at any location. The address is automatically increased to the next higher address after each byte of data is shifted out, so the whole memory can be read out with a single FRDDTR instruction. The address counter rolls over to 0 when the highest address is reached. Once writing FRDDTR instruction, the following address/dummy/data out will perform as 4-bit instead of previous 1-bit.

The sequence of issuing FRDDTR instruction is: CE# goes low → Sending FRDDTR instruction (1-bit per clock) → 24-bit interleave on IO1 & IO0 (4-bit per clock) as above → 4 dummy clocks (configurable, default is 4 clocks) on IO1 & IO0 → Data out interleave on IO1 & IO0 (4-bit per clock) → End FRDDTR operation via pulling CE# high at any time during data out (Please refer to Figures 8.86 and 8.87 for 2 x I/O Double Transfer Rate Read Mode Timing Waveform).

If AXh (where X is don't care) is input for the mode bits during dummy cycles, the device will enter AX read operation mode which enables subsequent FRDDTR execution skips command code. When the code is different from AXh (where X is don't care), the device exits the AX read operation. After finishing the read operation, device becomes ready to receive a new command.

If the FRDDTR instruction is issued while an Erase, Program or Write cycle is in process is in progress (WIP=1), the instruction will be rejected without any effect on the current cycle.

Figure 8.62 FRDDTR Sequence (BDh)

Notes:

1. If the mode bits=AXh (where X is don't care), it can execute the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

Figure 8.63 FRDDTR AX Read Sequence (BDh)

Notes:

1. If the mode bits=AXh (where X is don't care), it will keep executing the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

8.44 FAST READ QUAD IO DTR MODE OPERATION IN SPI MODE (FRQDTR, EDh)

The FRQDTR instruction enables Double Transfer Rate throughput on quad I/O of the device in read mode. A Quad Enable (QE) bit of status Register must be set to “1” before sending FRQDTR instruction.

The address (interleave on 4 I/O pins) is latched on both rising and falling edge of SCK, and data (interleave on 4 I/O pins) shift out on both rising and falling edge of SCK. The 8-bit address can be latched-in at one clock, and 8-bit data can be read out at one clock, which means four bits at the rising edge of clock, the other four bits at the falling edge of clock.

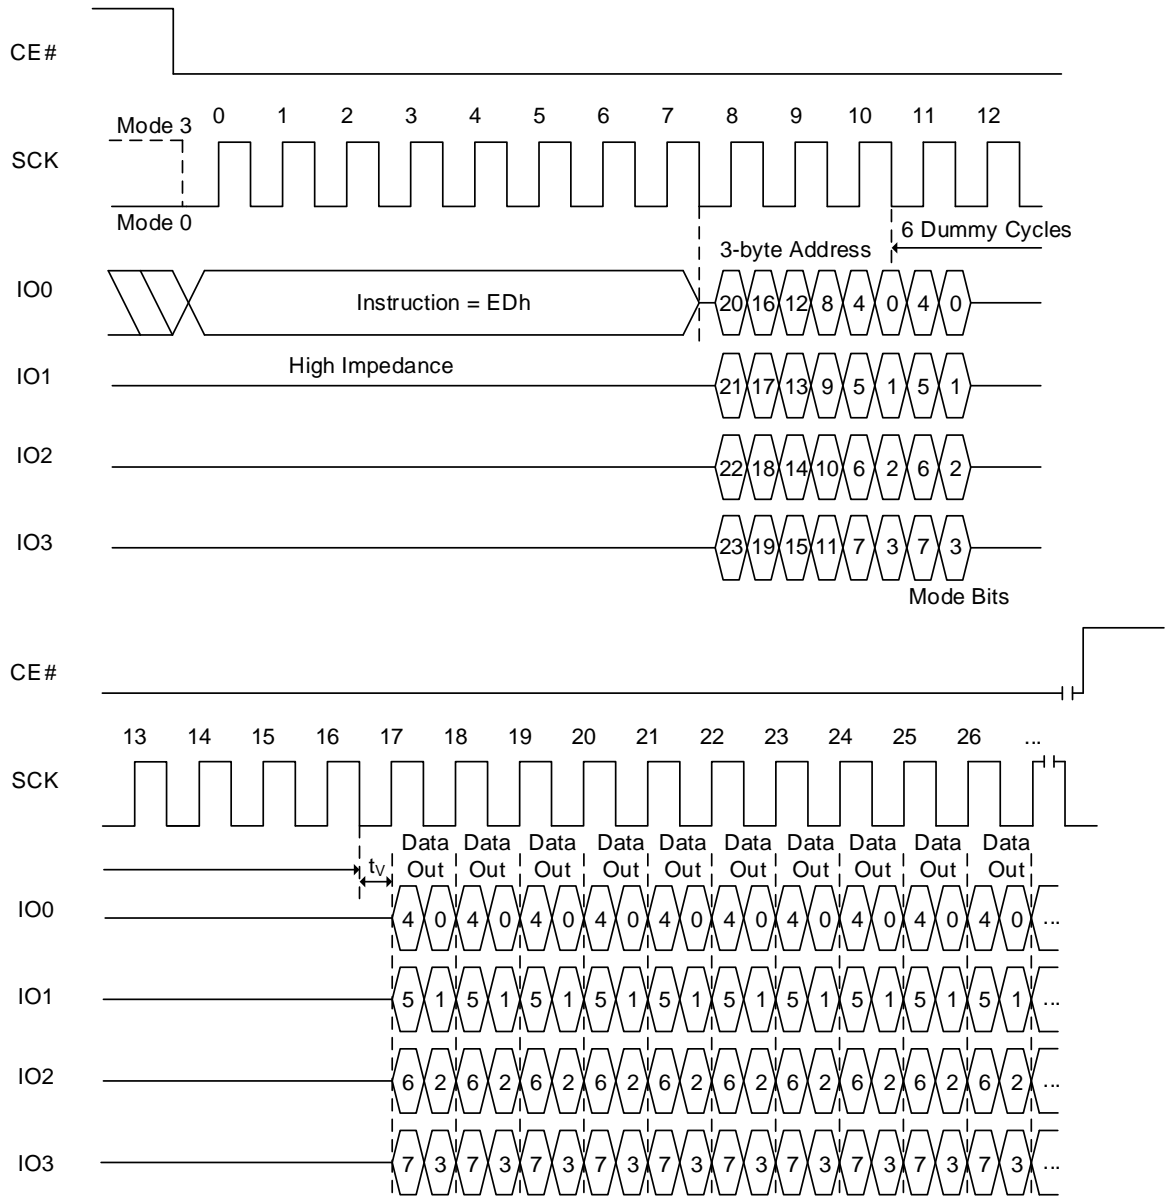

The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out with a single FRQDTR instruction. The address counter rolls over to 0 when the highest address is reached. Once writing FRQDTR instruction, the following address/dummy/data out will perform as 8-bit instead of previous 1-bit.

The sequence of issuing FRQDTR instruction is: CE# goes low → Sending FRQDTR instruction (1-bit per clock) → 24-bit interleave on IO3, IO2, IO1 & IO0 (8-bit per clock) as above → 6 dummy clocks (configurable, default is 6 clocks) → Data out interleave on IO3, IO2, IO1 & IO0 (8-bit per clock) → End FRQDTR operation by driving CE# high at any time during data out.

If AXh (where X is don't care) is input for the mode bits during dummy cycles, the device will enter AX read operation mode which enables subsequent FRQDTR execution skips command code. When the code is different from AXh (where X is don't care), the device exits the AX read operation. After finishing the read operation, device becomes ready to receive a new command.

If the FRQDTR instruction is issued while an Erase, Program or Write cycle is in process is in progress (WIP=1), the instruction will be rejected without any effect on the current cycle.

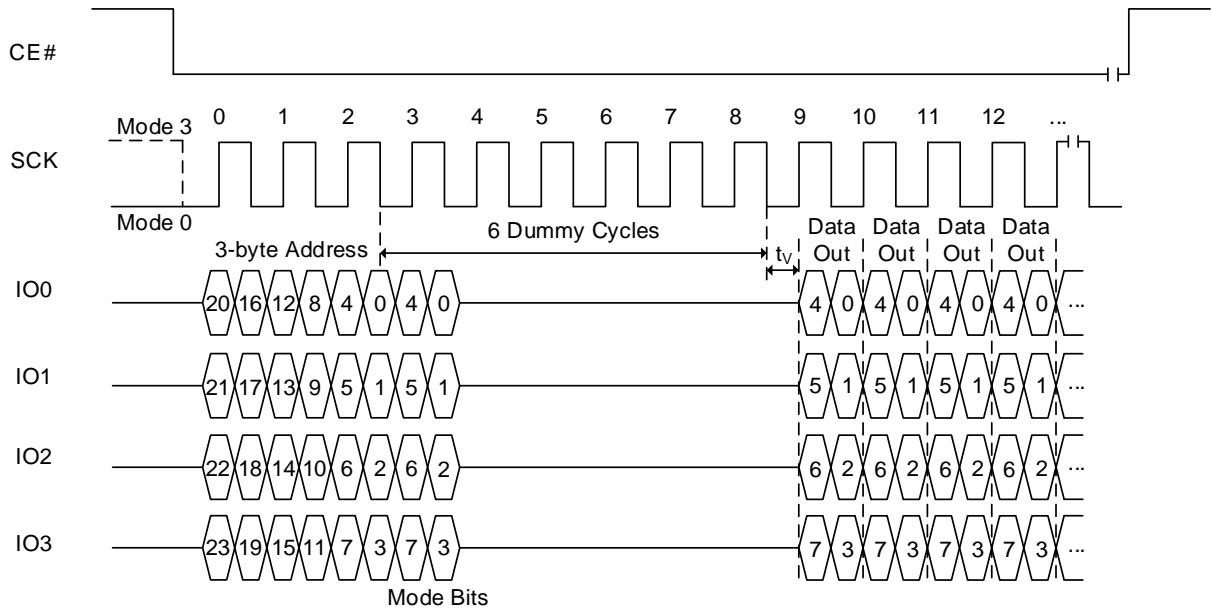

Figure 8.64 FRQDTR Sequence In SPI Mode (EDh)

Notes:

1. If the mode bits=AXh (where X is don't care), it can execute the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

Figure 8.65 FRQDTR AX Read Sequence (EDh)

Notes:

1. If the mode bits=AXh (where X is don't care), it will keep executing the AX read mode (without command). When the mode bits are different from AXh, the device exits the AX read operation.
2. Number of dummy cycles depends on clock speed. Detailed information in Table 6.11 Read Dummy Cycles.
3. Sufficient dummy cycles are required to avoid I/O contention. If the number of dummy cycles and AX bits cycles are same, then X should be Hi-Z.

8.45 SECTOR LOCK/UNLOCK FUNCTIONS

SECTOR UNLOCK OPERATION (SECUNLOCK, 26h)

The Sector Unlock command allows the user to select a specific sector to allow program and erase operations. This instruction is effective when the blocks are designated as write-protected through the BP0-BP3 bits in the Status Register and TBS bit in the Function Register. Only one sector can be enabled at any time. To enable a different sector, a previously enabled sector must be disabled by executing a Sector Lock command.

The instruction code is followed by a 24-bit specifying the target sector as above, but A0 through A11 are not decoded. The remaining sectors within the same block remain as read-only.

Figure 8.66 Sector Unlock Sequence In SPI Mode (26h)

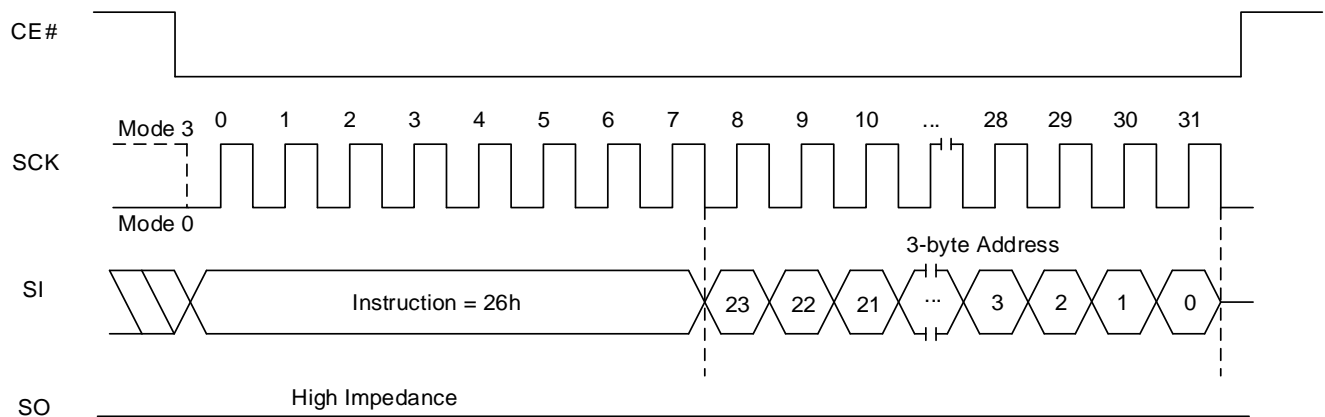

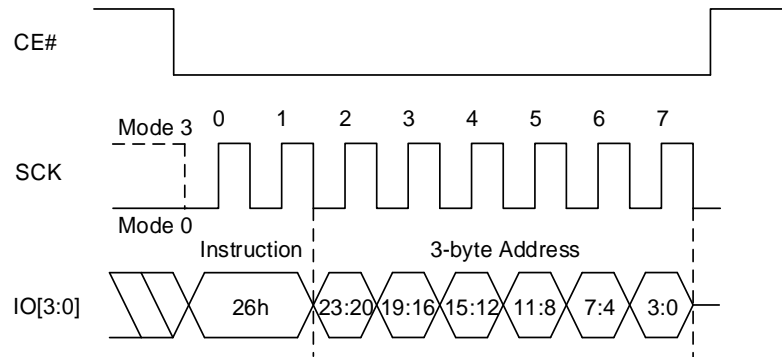

Figure 8.67 Sector Unlock Sequence In QPI Mode (26h)

SECTOR LOCK OPERATION (SELOCK, 24h)

The Sector Lock command relocks a sector that was previously unlocked by the Sector Unlock command. The instruction code does not require an address to be specified, as only one sector can be enabled at a time. The remaining sectors within the same block remain in read-only mode.

Figure 8.68 Sector Lock Sequence In SPI Mode

Figure 8.69 Sector Lock Sequence In QPI Mode

8.46 AUTOBOOT

SPI devices normally require 32 or more cycles of command and address shifting to initiate a read command. And, in order to read boot code from an SPI device, the host memory controller or processor must supply the read command from a hardwired state machine or from some host processor internal ROM code.

Parallel NOR devices need only an initial address, supplied in parallel in a single cycle, and initial access time to start reading boot code.

The AutoBoot feature allows the host memory controller to take boot code from the device immediately after the end of reset, without having to send a read command. This saves 32 or more cycles and simplifies the logic needed to initiate the reading of boot code.

- As part of the Power-up Reset, Hardware Reset, or Software Reset process the AutoBoot feature automatically starts a read access from a pre-specified address. At the time the reset process is completed, the device is ready to deliver code from the starting address. The host memory controller only needs to drive CE# signal from high to low and begin toggling the SCK signal. The device will delay code output for a pre-specified number of clock cycles before code streams out.
 - The Auto Boot Start Delay (ABSD) field of the AutoBoot register specifies the initial delay if any is needed by the host.
 - The host cannot send commands during this time.
 - If QE bit (Bit 6) in the Status Register is set to “1”, Fast Read Quad I/O operation will be selected and initial delay is the same as dummy cycles of Fast Read Quad I/O Read operation. If it is set to “0”, Fast Read operation will be applied and initial delay is the same as dummy cycles of Fast Read operation.
- The starting address of the boot code is selected by the value programmed into the AutoBoot Start Address (ABSA) field of the AutoBoot Register.
 - Data will continuously shift out until CE# returns high.
- At any point after the first data byte is transferred, when CE# returns high, the SPI device will reset to standard SPI mode; able to accept normal command operations.
 - A minimum of one byte must be transferred.
 - AutoBoot mode will not initiate again until another power cycle or a reset occurs.
- An AutoBoot Enable bit (ABE) is set to enable the AutoBoot feature.

The AutoBoot register bits are non-volatile and provide:

- The starting address set by the AutoBoot Start Address (ABSA).
- The number of initial delay cycles, set by the AutoBoot Start Delay (ABSD) 4-bit count value.

Figure 8.70 AutoBoot Sequence (QE = 0)

Figure 8.71 AutoBoot Sequence (QE = 1)

AUTOBOOT REGISTER READ OPERATION (RDABR, 14h)

The AutoBoot Register Read command is shifted in. Then the 32bit AutoBoot Register is shifted out, least significant byte first, most significant bit of each byte first. It is possible to read the AutoBoot Register continuously by providing multiples of 32bits.

RDABR operation is valid only at SPI mode only.

Figure 8.72 RDABR Sequence In SPI Mode

AUTOBOOT REGISTER WRITE OPERATION (WRABR, 15h)

Before the WRABR command can be accepted, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The WRABR command is entered by shifting the instruction and the data bytes, least significant byte first, most significant bit of each byte first. The WRABR data is 32bits in length.

CE# must be driven high after the 32nd bit of data has been latched. If not, the WRABR command is not executed. As soon as CE# is driven high, the WRABR operation is initiated. While the WRABR operation is in progress, Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is "1" during the WRABR operation, and is "0" when it is completed. When the WRABR cycle is completed, the WEL is set to "0".

Figure 8.73 WRABR Sequence In SPI Mode

Figure 8.74 WRABR Sequence In QPI Mode

8.47 READ DYB OPERATION (RDDYB, FAh)

The instruction is used to read Dynamic Protection Bit (DYB) status of the given sector/block. The instruction code is entered first, followed by the 24-bit address selecting location zero within the desired sector/block as above. Then the 8-bit DYB access register contents are shifted out. Each bit (SPI) or four bits (QPI) are shifted out at the SCK frequency by the falling edge of the SCK signal. It is possible to read the same DYB access register continuously by providing multiples of eight bits. The address of the DYB register does not increment so this is not a means to read the entire DYB array. Each location must be read with a separate Read DYB instruction.

Note: Data must be either 00h (protected) or FFh (unprotected).

Figure 8.75 Read DYB Sequence In SPI Mode (FAh)

Figure 8.76 Read DYB Sequence In QPI Mode (FAh)

8.48 WRITE DYB OPERATION (WRDYB, FBh)

Before the WRDYB command can be accepted by the device, a standard Write Enable (06h) instruction must previously have been executed for the device to accept Write DYB instruction (Status Register bit WEL must equal 1).

The WRDYB command is entered by driving CE# low, followed by the instruction code, the 24-bit selecting location zero within the desired sector/block as above, then the data byte. The DYB Access Register is one data byte in length.

CE# must be driven high after the eighth bit of data has been latched in. As soon as CE# is driven high, the WRDYB operation is initiated.

Note: Data must be either 00h (protected) or FFh (unprotected).

Figure 8.77 Write DYB Sequence In SPI Mode (FBh)

Figure 8.78 Write DYB Sequence In QPI Mode (FBh)

8.49 READ PPB OPERATION (RDPPB, FCh)

The instruction code is shifted into SI by the rising edges of the SCK signal, followed by the 24-bit selecting location zero within the desired sector/block as above. Then the 8-bit PPB Access Register contents are shifted out on SO. The RDPPB is supporting only SPI, not supporting QPI.

It is possible to read the same PPB Access Register continuously by providing multiples of eight bits. The address of the PPB Access Register does not increment so this is not a means to read the entire PPB array. Each location must be read with a separate Read PPB command.

Note: Data must be either 00h (protected) or FFh (unprotected).

Figure 8.79 Read PPB Sequence (FCh)

8.50 PROGRAM PPB OPERATION (PGPPB, FDh)

Before the Program PPB (PGPPB) command is sent, a Write Enable (WREN) command must be issued. After the WREN command has been decoded, the device will set the Write Enable Latch (WEL) in the Status Register.

The PGPPB command is entered by driving CE# low, followed by the instruction code, followed by the 24-bit address selecting location zero within the desired sector/block as above.

The PGPPB command affects the WIP bit in the same manner as any other programming operation. CE# must be driven high after the last bit of address has been latched in. As soon as CE# is driven high, the PGPPB operation is initiated. While the PGPPB operation is in progress, the Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is "1" during the PGPPB operation, and is "0" when it is completed. When the PGPPB operation is completed, the WEL is set to "0".

Note: Data must be either 00h (protected) or FFh (unprotected).

Figure 8.80 Program PPB Sequence In SPI Mode (FDh)

Figure 8.81 Program PPB Sequence In QPI Mode (FDh)

8.51 ERASE PPB OPERATION (ERPPB, E4h)

The Erase PPB (ERPPB) command sets all PPB bits to “1”. Before the ERPPB command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The instruction code is shifted in by the rising edges of the SCK signal. CE# must be driven high after the eighth bit of the instruction byte has been latched in. This will initiate the beginning of internal erase cycle, which involves the pre-programming and erase of the entire PPB memory array. Without CE# being driven high after the eighth bit of the instruction, the PPB erase operation will not be executed.

With the internal erase cycle in progress, the user can read the value of the Write In Progress (WIP) bit to check if the operation has been completed. The WIP bit will indicate “1” when the erase cycle is in progress and “0” when the erase cycle has been completed. When the ERPPB operation is completed, the WEL is set to “0”. Erase suspend is not allowed during PPB Erase.

Figure 8.82 Erase PPB Sequence In SPI Mode

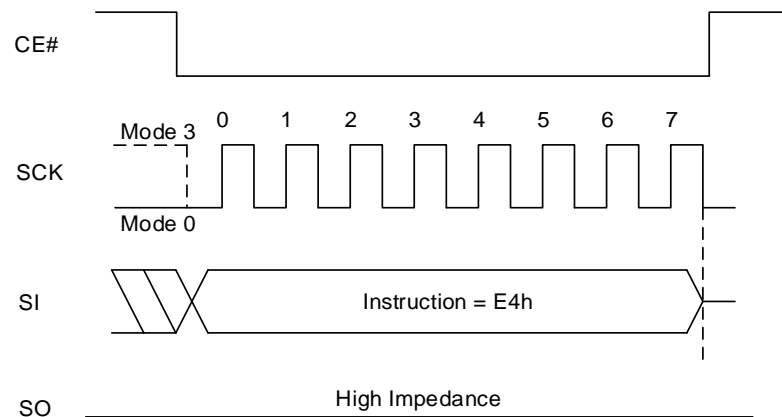

Figure 8.83 Erase PPB Sequence In QPI Mode

8.52 READ ASP OPERATION (RDASP, 2Bh)

The RDASP instruction code is shifted in by the rising edge of the SCK signal. Then the 16-bit ASP register contents is shifted out, least significant byte first, most significant bit of each byte first. Each bit is shifted out at the SCK frequency by the falling edge of the SCK signal. It is possible to read the ASP register continuously by providing multiples of 16 bits.

Figure 8.84 Read ASP Sequence In SPI Mode

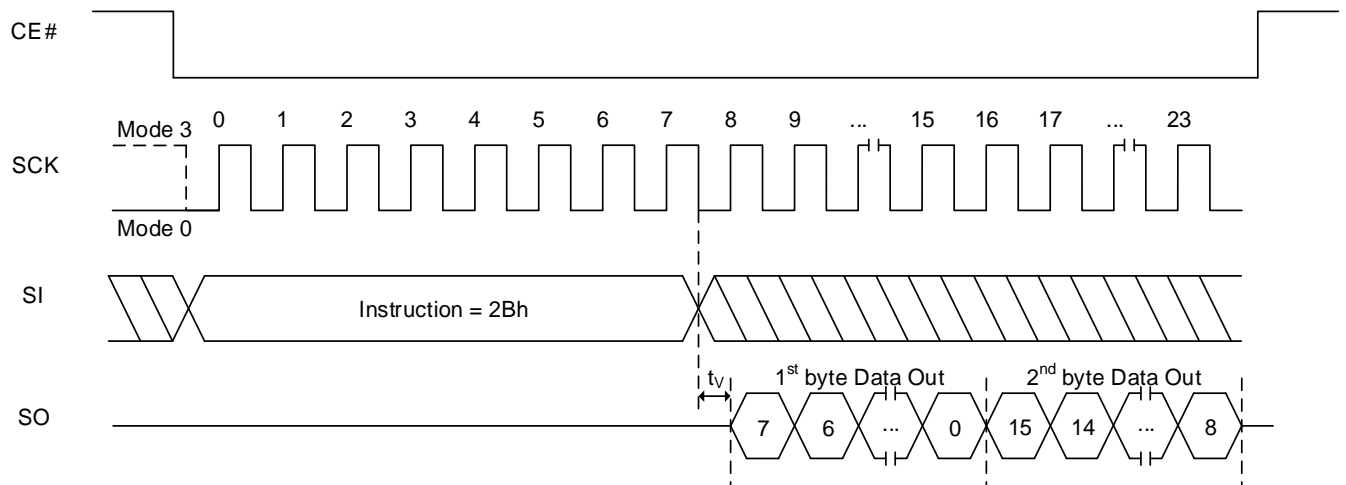

Figure 8.85 Read ASP Sequence In QPI Mode

8.53 PROGRAM ASP OPERATION (PGASP, 2Fh)

Before the Program ASP (PGASP) command can be accepted by the device, a Write Enable (WREN) command must be issued. After the WREN command has been decoded, the device will set the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The PGASP command is entered by driving CE# low, followed by the instruction code and two data bytes, least significant byte first, most significant bit of each byte first. The ASP Register is two data bytes in length. The PGASP command affects the Write In Progress (WIP) bit in the same manner as any other programming operation.

CE# input must be driven high after the sixteenth bit of data has been latched in. If not, the PGASP command is not executed. As soon as CE# is driven high, the PGASP operation is initiated. While the PGASP operation is in progress, the Status Register or the Extended Read Register may be read to check the value of WIP bit. The WIP bit is "1" during the PGASP operation, and is "0" when it is completed. When the PGASP operation is completed, the WEL is set to "0".

Figure 8.86 Program ASP Sequence In SPI Mode

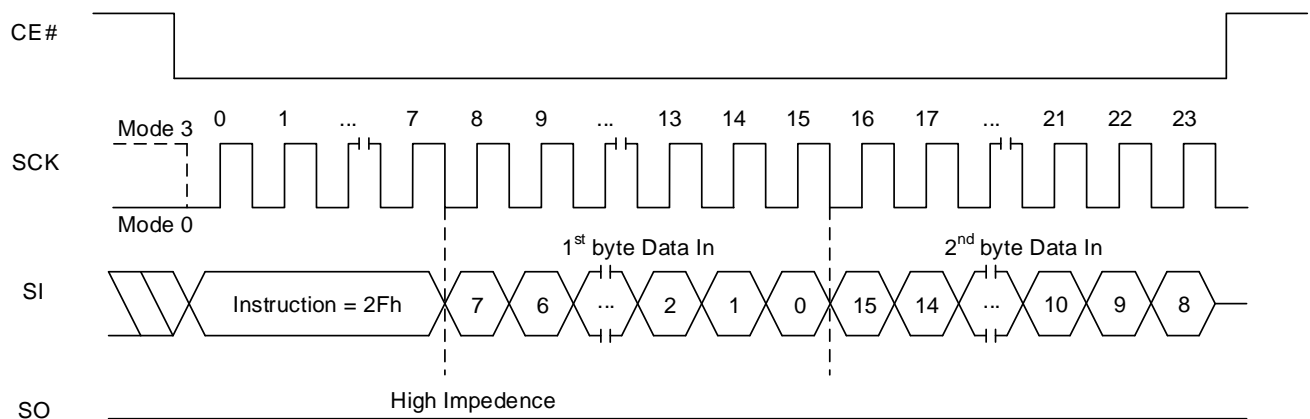

Figure 8.87 Program ASP Sequence In QPI Mode

8.54 READ PPB LOCK BIT OPERATION (RDPLB, A7h)

The Read PPB Lock Bit (RDPLB) command allows the PPB Lock Register contents to be read. It is possible to read the PPB Lock Register continuously by providing multiples of eight bits. The PPB Lock Register contents may only be read when the device is in standby state with no other operation in progress. It is recommended to check the Write In Progress (WIP) bit before issuing a new command to the device.

RDPLB operation is valid only at SPI mode only.

Figure 8.88 Read PPB Lock Bit Sequence In SPI Mode

8.55 WRITE PPB LOCK BIT OPERATION (WRPLB, A6h)

The Write PPB Lock Bit (WRPLB) command only clears the PPB Lock (PPBLK) bit to “0” in the Persistent Protection mode. Before the WRPLB command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The WRPLB command is entered by driving CE# low, followed by the instruction code. CE# must be driven high after the eighth bit of instruction has been latched in. If not, the WRPLB command is not executed. As soon as CE# is driven high, the WRPLB operation is initiated. While the WRPLB operation is in progress, the Status Register or Extended Read Register may still be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the WRPLB operation, and is “0” when it is completed. When the WRPLB operation is completed, the WEL is set to “0”.

Figure 8.89 Write PPB Lock Bit Sequence In SPI Mode

Figure 8.90 Write PPB Lock Bit Sequence In QPI Mode

8.56 SET FREEZE BIT OPERATION (SFRZ, 91h)

The Set FREEZE Bit (SFRZ) command only sets FREEZE (PPB Lock Register bit7) to “1”. Before the SFRZ command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The SFRZ command is entered by driving CE# low, followed by the instruction code. CE# must be driven high after the eighth bit of instruction has been latched in. If not, the SFRZ command is not executed. As soon as CE# is driven high, the SFRZ operation is initiated. While the SFRZ operation is in progress, the Status Register or Extended Read Register may still be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the SFRZ operation, and is “0” when it is completed. When the SFRZ operation is completed, the WEL is set to “0”.

Figure 8.91 Set FREEZE Bit Sequence In SPI Mode

Figure 8.92 Set FREEZE Bit Sequence In QPI Mode

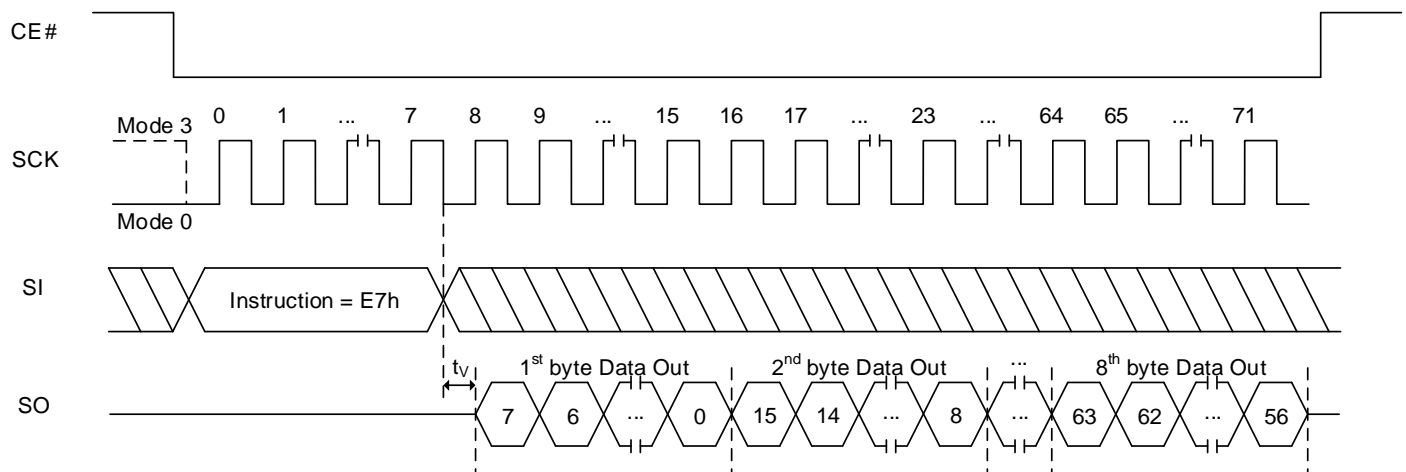

8.57 READ PASSWORD OPERATION (RDPWD, E7h)

The correct password value may be read only after it is programmed and before the Password Mode has been selected by programming the Password Protection Mode bit to “0” in the ASP Register (ASP [2]). After the Password Protection Mode is selected the RDPWD command is ignored.

The RDPWD command is shifted in. Then the 64-bit Password is shifted out, least significant byte first, most significant bit of each byte first. Each bit is shifted out at the SCK frequency by the falling edge of the SCK signal. It is possible to read the Password continuously by providing multiples of 64bits.

RDPWD operation is valid only at SPI mode only.

Figure 8.93 Read password Sequence In SPI Mode

8.58 PROGRAM PASSWORD OPERATION (PGPWD, E8h)

Before the Program Password (PGPWD) command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device which sets the Write Enable Latch (WEL) to enable the PGPWD operation. The password can only be programmed before the Password Mode is selected by programming the Password Protection Mode bit to “0” in the ASP Register (ASP [2]). After the Password Protection Mode is selected the PGPWD command is ignored.

The PGPWD command is entered by driving CE# low, followed by the instruction code and the password data bytes, least significant byte first, most significant bit of each byte first. The password is 64bits in length.

CE# must be driven high after the 64th bit of data has been latched. If not, the PGPWD command is not executed. As soon as CE# is driven high, the PGPWD operation is initiated. While the PGPWD operation is in progress, the Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the PGPWD operation, and is “0” when it is completed. When the PGPWD operation is completed, the Write Enable Latch (WEL) is set to “0”.

Figure 8.94 Program Password Sequence In SPI Mode

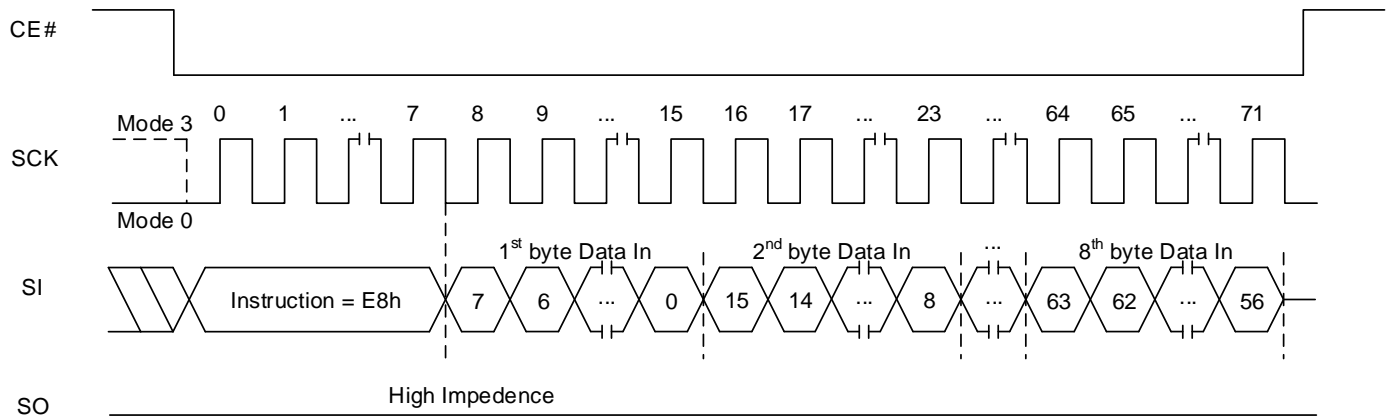

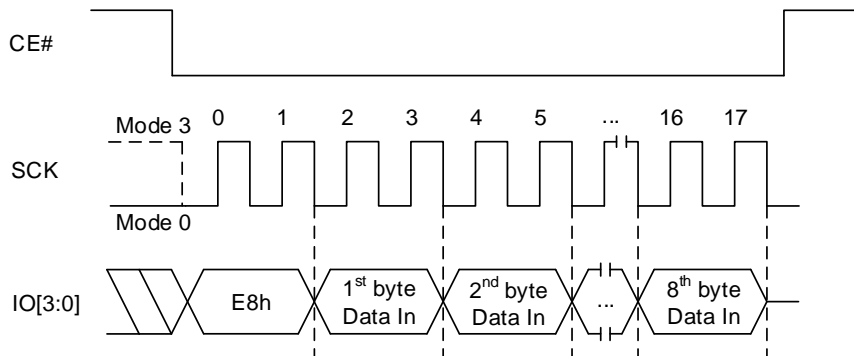

Figure 8.95 Program Password Sequence In QPI Mode

8.59 UNLOCK PASSWORD OPERATION (UNPWD, E9h)

In the Password Protection mode, the PPB Lock bit is cleared to “0” during POR or Hardware Reset. The PPB Lock bit can only be set to 1 by the Unlock Password command.

A Write Enable (WREN) command is not required prior to UNPWD command

The UNPWD command is entered by driving CE# low, followed by the instruction code and the password data bytes, least significant byte first, most significant bit of each byte first. The password is 64bits in length.

CE# must be driven high after the 64th bit of data has been latched. If not, the UNPWD command is not executed. As soon as CE# is driven high, the UNPWD operation is initiated. While the UNPWD operation is in progress, the Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the UNPWD operation, and is “0” when it is completed.

If the UNPWD command supplied password does not match the hidden password in the Password Register, the UNPWD command is ignored. This returns the device to standby state, ready for a new command such as a retry of the UNPWD command. If the password does match, the PPB Lock bit is set to “1”.

Figure 8.96 Unlock Password Sequence In SPI Mode

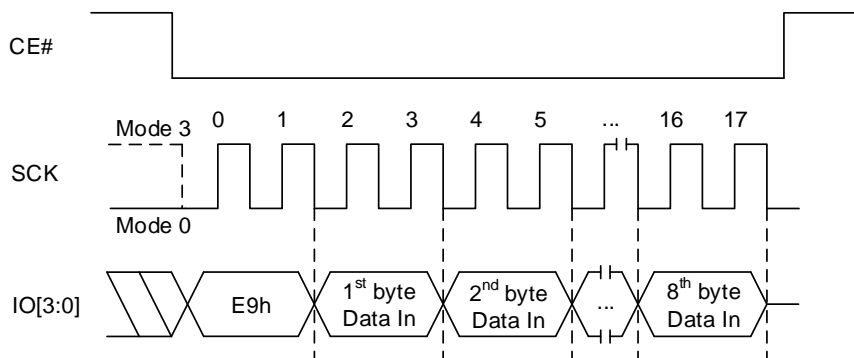

Figure 8.97 Unlock Password Sequence In SPI Mode

8.60 GANG SECTOR/BLOCK LOCK OPERATION (GBLK, 7Eh)

The Gang Sector/Block Lock (GBLK) instruction provides a quick method to set all DYB (Dynamic Protection Bit) bits to “0” at once.

Before the GBLK (7Eh) command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The sequence of issuing GBLK instruction is: drive CE# low → send GBLK instruction code → drive CE# high. The instruction code will be shifted into the device on the rising edge of SCK.

The GBLK command is accepted in both SPI and QPI mode. The CE# must go high exactly at the byte boundary, otherwise, the instruction will be ignored. While the GBLK operation is in progress, the Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the GBLK operation, and is “0” when it is completed.

Figure 8.98 Gang Sector/Block Lock Sequence In SPI Mode

Figure 8.99 Gang Sector/Block Lock Sequence In QPI Mode

8.61 GANG SECTOR/BLOCK UNLOCK OPERATION (GBUN, 98h)

The Gang Sector/Block Unlock (GBUN) instruction provides a quick method to clear all DYB (Dynamic Protection Bit) bits to “1” at once.

Before the GBUN (98h) command can be accepted by the device, a Write Enable (WREN) command must be issued and decoded by the device, which sets the Write Enable Latch (WEL) in the Status Register to enable any write operations.

The sequence of issuing GBUN instruction is: drive CE# low → send GBUN instruction code → drive CE# high. The instruction code will be shifted into the device on the rising edge of SCK.

The GBUN command is accepted in both SPI and QPI mode. The CE# must go high exactly at the byte boundary, otherwise, the instruction will be ignored and not be executed. While the GBUN operation is in progress, the Status Register or Extended Read Register may be read to check the value of the Write In Progress (WIP) bit. The WIP bit is “1” during the GBUN operation, and is “0” when it is completed.

Figure 8.100 Gang Sector/Block Unlock Sequence In SPI Mode

9. ELECTRICAL CHARACTERISTICS

9.2 ABSOLUTE MAXIMUM RATINGS ⁽¹⁾

Storage Temperature		-65°C to +150°C
Surface Mount Lead Soldering Temperature	Standard Package	240°C 3 Seconds
	Lead-free Package	260°C 3 Seconds
Input Voltage with Respect to Ground on All Pins		-0.5V to $V_{CC} + 0.5V$
All Output Voltage with Respect to Ground		-0.5V to $V_{CC} + 0.5V$
V_{CC}	IS25LP	-0.5V to +6.0V
	IS25WP	-0.5V to +2.5V

Note:

1. Applied conditions greater than those listed in “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

9.3 OPERATING RANGE

Operating Temperature	Extended Grade E	-40°C to 105°C
	Automotive Grade A3	-40°C to 125°C
V_{CC} Power Supply	IS25LP	2.3V (V _{MIN}) – 3.6V (V _{MAX}); 3.0V (Typ)
	IS25WP	1.65V (V _{MIN}) –1.95V (V _{MAX}); 1.8V (Typ)

9.4 DC CHARACTERISTICS

(Under operating range)

Symbol	Parameter		Condition	Min	Typ ⁽²⁾	Max	Units
I _{CC1}	V _{CC} Active Read current ⁽³⁾		NORD at 80MHz		7	8	mA
			FRD Single at 166MHz		9	11	
			FRD Dual at 166MHz		10	12

			FRD Quad DTR at 80MHz		11	12	
I _{CC2}	V _{CC} Program Current		CE# = V _{CC}	85°C	25	30 ⁽⁶⁾	mA
				105°C		30 ⁽⁶⁾	
				125°C		30	
I _{CC3}	V _{CC} WRSR Current		CE# = V _{CC}	85°C	25	30 ⁽⁶⁾	mA
				105°C		30 ⁽⁶⁾	
				125°C		30	
I _{CC4}	V _{CC} Erase Current (SER/4SER/BER32/4BER32/ BER64/4BER64)		CE# = V _{CC}	85°C	25	30 ⁽⁶⁾	mA
				105°C		30 ⁽⁶⁾	
				125°C		30	
I _{CC5}	V _{CC} Erase Current (CE)		CE# = V _{CC}	85°C	25	30 ⁽⁶⁾	mA
				105°C		30 ⁽⁶⁾	
				125°C		30	
I _{SB1}	V _{CC} Standby Current CMOS		CE# = V _{CC} , V _{IN} = GND or V _{CC} ⁽⁴⁾	85°C	8	25 ⁽⁶⁾	μA
				105°C		40 ⁽⁶⁾	
				125°C		60	
I _{SB2}	Deep power down current	IS25LP	CE# = V _{CC} , V _{IN} = GND or V _{CC} ⁽⁴⁾	85°C	5	20 ⁽⁶⁾	μA
				105°C		25 ⁽⁶⁾	
				125°C		35	
		IS25WP		85°C	1	5 ⁽⁶⁾	
				105°C		12 ⁽⁶⁾	
				125°C		25	
I _{LI}	Input Leakage Current		V _{IN} = 0V to V _{CC}			±1 ⁽⁵⁾	μA
I _{LO}	Output Leakage Current		V _{IN} = 0V to V _{CC}			±1 ⁽⁵⁾	μA
V _{IL} ⁽¹⁾	Input Low Voltage			-0.5		0.3V _{CC}	V
V _{IH} ⁽¹⁾	Input High Voltage			0.7V _{CC}		V _{CC} + 0.3	V
V _{OL}	Output Low Voltage		I _{OL} = 100 μA			0.2	V
V _{OH}	Output High Voltage		I _{OH} = -100 μA	V _{CC} - 0.2			V

Notes:

1. Maximum DC voltage on input or I/O pins is $V_{CC} + 0.5V$. During voltage transitions, input or I/O pins may overshoot V_{CC} by $+2.0V$ for a period of time not to exceed 20ns. Minimum DC voltage on input or I/O pins is $-0.5V$. During voltage transitions, input or I/O pins may undershoot GND by $-2.0V$ for a period of time not to exceed 20ns.
2. Typical values are included for reference only and are not guaranteed or tested. Typical values are measured at $V_{CC} = V_{CC} (Typ)$, $T_A=25^{\circ}C$.
3. Outputs are unconnected during reading data so that output switching current is not included.
4. $V_{IN} = V_{CC}$ for the dedicated RESET# pin (or ball).
5. The Max of I_{LI} and I_{LO} for the dedicated RESET# pin (or ball) is $\pm 2 \mu A$.
6. These parameters are characterized and are not 100% tested.

9.5 AC MEASUREMENT CONDITIONS

Symbol	Parameter	Min	Max	Units
CL	Load Capacitance up to 104MHz/52MHz DTR		30	pF
	Load Capacitance up to 166MHz/80MHz DTR		15	pF
TR,TF	Input Rise and Fall Times		5	ns
VIN	Input Pulse Voltages	0.2V _{CC} to 0.8V _{CC}		V
VREFI	Input Timing Reference Voltages	0.3V _{CC} to 0.7V _{CC}		V
VREFO	Output Timing Reference Voltages	0.5V _{CC}		V

t _{HWRST} ⁽¹⁾	Hardware Reset recovery time			35	μs

Notes:

1. These parameters are characterized and not 100% tested.
2. Typical values are included for reference only and are not guaranteed or tested. Typical values are measured at V_{CC} = V_{CC} (Typ), TA=25°C.
3. Only applicable as a constraint for a WRITE STATUS REGISTER command when SRWD is set at 1.
4. Values are guaranteed by characterization and not 100% tested in production.
5. 166MHz at - 40°C to 105°C

9.9 POWER-UP AND POWER-DOWN

At Power-up and Power-down, the device must be NOT SELECTED until Vcc reaches at the right level. (Adding a simple pull-up resistor on CE# is recommended.)

Power up timing

Symbol	Parameter		Min.	Max	Unit
$t_{VCE}^{(1)}$	Vcc(min) to CE# Low		300		us
$V_{WI}^{(1)}$	Write Inhibit Voltage	IS25LP		2.1	V
		IS25WP		1.4	

Note: These parameters are characterized and not 100% tested.

9.10 PROGRAM/ERASE PERFORMANCE

Parameter	Typ	Max	Unit
Sector Erase Time (4Kbyte)	100	300	ms
Block Erase Time (32Kbyte)	0.14	0.5	s
Block Erase Time (64Kbyte)	0.17	1.0	s
Chip Erase Time	18	45	s
Page Programming Time	0.2	0.8	ms
Byte Program	8	40	μs

Note: These parameters are characterized and not 100% tested.

9.11 RELIABILITY CHARACTERISTICS

Parameter	Min	Max	Unit	Test Method
Endurance	100,000	-	Cycles	JEDEC Standard A117
Data Retention	20	-	Years	JEDEC Standard A117
Latch-Up	-100	+100	mA	JEDEC Standard 78

Note: These parameters are characterized and not 100% tested.
