

Low-power quad operational amplifiers

QFN16 3x3

TSSOP14

SO14

Features

- Wide gain bandwidth: 1.3 MHz
- Input common mode voltage range includes ground
- Large voltage gain: 100 dB
- Very low supply current/amplifier: 375 μ A
- Low input bias current: 20 nA
- Low input voltage: 3 mV max.
- Low input offset current: 2 nA
- Wide power supply range:
 - Single supply: 3 V to 30 V
 - Dual supplies: \pm 1.5 V to \pm 15 V

Description

The [LM124](#), [LM224x](#) and [LM324x](#) consist of four independent, high gain operational amplifiers with frequency compensation implemented internally. They operate from a single power supply over a wide range of voltages.

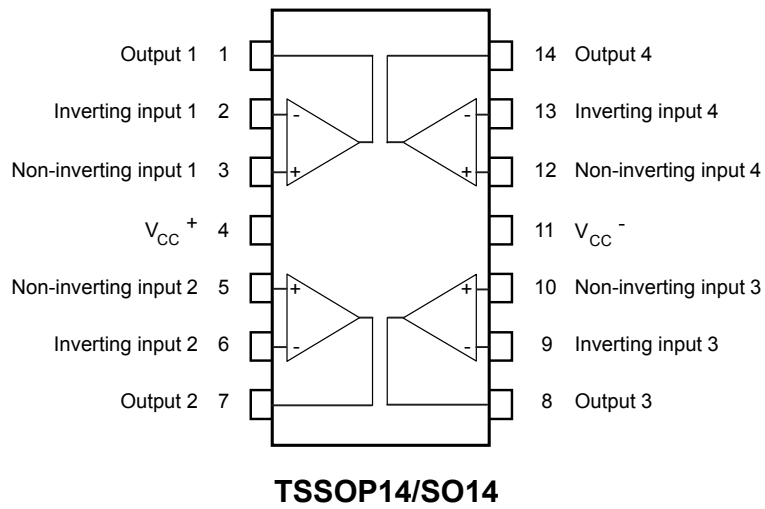

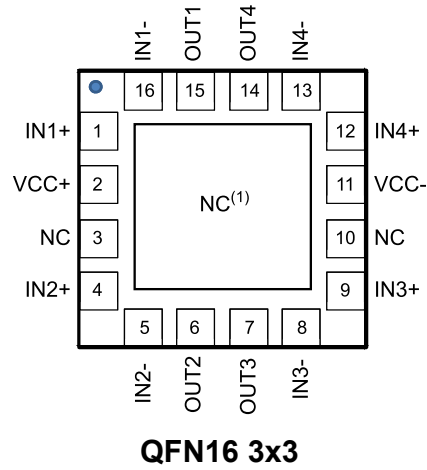

Operation from split power supplies is also possible and the low-power supply current drain is independent of the magnitude of the power supply voltage.

- Neither of the input voltages must exceed the magnitude of (V_{CC}^+) or (V_{CC}^-).
- Short-circuits from the output to V_{CC} can cause excessive heating if $V_{CC} > 15$ V. The maximum output current is approximately 40 mA independent of the magnitude of V_{CC} . Destructive dissipation can result from simultaneous short-circuits on all amplifiers.
- This input current only exists when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistor becoming forward biased and thereby acting as an input diode clamp. In addition to this diode action, there is also an NPN parasitic action on the IC chip. This transistor action can cause the output voltages of the op amps to go to the V_{CC} voltage level (or to ground for a large overdrive) for the time during which an input is driven negative. This is not destructive and normal output starts up again for input voltages higher than -0.3 V.
- Short-circuits can cause excessive heating. Destructive dissipation can result from simultaneous short-circuits on all amplifiers. These are typical values given for a single layer board (except for TSSOP which is a two-layer board).
- Human body model: 100 pF discharged through a 1.5 k Ω resistor between two pins of the device, done for all couples of pin combinations with other pins floating.
- Machine model: a 200 pF cap is charged to the specified voltage, then discharged directly between two pins of the device with no external series resistor (internal resistor $< 5 \Omega$), done for all couples of pin combinations with other pins floating.

1. V_o = 1.4 V, R_s = 0 Ω, 5 V < V_{CC} + < 30 V, 0 < V_{ic} < V_{CC} + - 1.5 V
2. The direction of the input current is out of the IC. This current is essentially constant, independent of the state of the output so there is no load change on the input lines.
3. The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than 0.3 V. The upper end of the common-mode voltage range is (V_{CC} +) - 1.5 V, but either or both inputs can go to 32 V without damage.
4. Due to the proximity of external components, ensure that there is no coupling originating from stray capacitance between these external parts. Typically, this can be detected at higher frequencies because this type of capacitance increases.

For $\frac{R_1}{R_2} = \frac{R_4}{R_3}$ CMRR depends on the following resistor ratio match

$$V_o = \left(1 + \frac{R_4}{R_3}\right) (V_2 - V_1)$$

As shown $V_o = 2 * (V_2 - V_1)$
