## Programmable transient voltage suppressor for SLIC protection

TIP or RING TIP or RING Ga RIN

|--|

### **Features**

- Programmable transient suppressor
- Wide negative firing voltage range:
  - V<sub>Gn</sub> = -175 V max.
- Low dynamic switching voltages:
- V<sub>FP</sub> and V<sub>DGL</sub>
- Low gate triggering current:  $I_{GT}$  = 5 mA max.
- Peak pulse current: IPP = 40 A (5/310 µs)
- Holding current:  $I_H = 150 \text{ mA min.}$
- Benefits:
  - A Trisil is not subject to ageing and provides a fail-safe mode in short circuit for a better protection.
  - Trisils are used to help equipment to meet various standards such as UL60950, IEC 60950 / CSA C22.2, UL1459 and TIA-968-A (formerly FCC part 68)
  - Trisils have UL94 V0 resin approved (Trisils are UL497B approved file: E136224)

## **Description**

These devices have been especially designed to protect new high voltage, as well as classical SLICs, against transient overvoltages.

Positive overvoltages are clamped by 2 diodes. Negative surges are suppressed by 2 thyristors, their breakdown voltage being referenced to -V<sub>BAT</sub> through the gate.

These components present a very low gate triggering current (IGT) in order to reduce the current consumption on printed circuit board during the firing phase.

TL	Maximum temperature	Maximum temperature for soldering during 10 s				

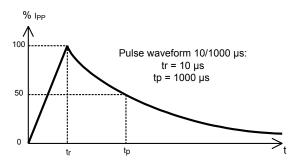

### Table 3. Absolute ratings (T<sub>amb</sub> = 25 °C)

1. The rated current values may be applied either to the Ring to GND or to the Tip to GND terminal pairs. Additionally, the four terminal pairs may have their rated current values applied simultaneously (in this case the GND terminal current will be four times the rated current value of an individual terminal pair). Both GND pins must be connected to GND.

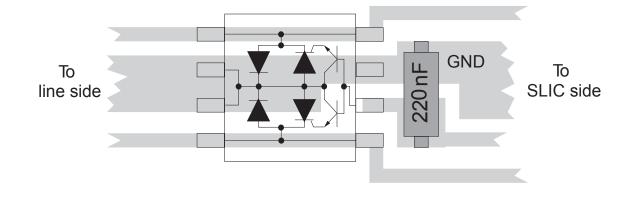

#### Figure 3. LCP concept behavior

Figure 3 shows the classical protection circuit using the LCP crowbar concept. This topology has been developed to protect the new high voltage SLICs. It allows to program the negative firing threshold while the positive clamping value is fixed at GND.

When a negative surge occurs on one wire (L1 for example) a current IG flows through the base of the transistor T1 and then injects a current in the gate of the thyristor Th1. Th1 fires and all the surge current flows through the ground. After the surge when the current flowing through Th1 becomes less negative than the holding current IH, then Th1 switches off.

When a positive surge occurs on one wire (L1 for example) the diode D1 conducts and the surge current flows through the ground.

#### Figure 4. Example of PCB layout based on LCP1521S protection

Figure 4 shows the classical PCB layout used to optimize line protection.

The capacitor C is used to speed up the crowbar structure firing during the fast surge edges.

This allows minimization of the dynamic breakover voltage at the SLIC Tip and Ring inputs during fast strikes. Note that this capacitor is generally present around the SLIC -  $V_{bat}$  pin.

So to be efficient it has to be as close as possible from the LCP Gate pin and from the reference ground track (or plan) (see Figure 4). The optimized value for C is 220 nF.

The series resistors Rs1 and Rs2 designed in Figure 3 represent the fuse resistors or the PTC which are mandatory to withstand the power contact or the power induction tests imposed by the various country standards. Taking into account this fact the actual lightning surge current flowing through the LCP is equal to:

- surge = V  $_{surge}$  / (R<sub>g</sub> + R<sub>s</sub>) with:
  - V surge = peak surge voltage imposed by the standard
  - R<sub>a</sub> = series resistor of the surge generator
  - R<sub>s</sub> = series resistor of the line card (e.g. PTC)

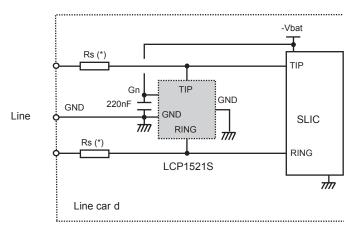

E.g. For a line card with 30  $\Omega$  of series resistors which has to be qualified under GR1089 core 1000V 10/1000  $\mu s$  surge, the actual current through the LCP is equal to:

I<sub>surge</sub> = 1000 / (10 + 30) = 25 A

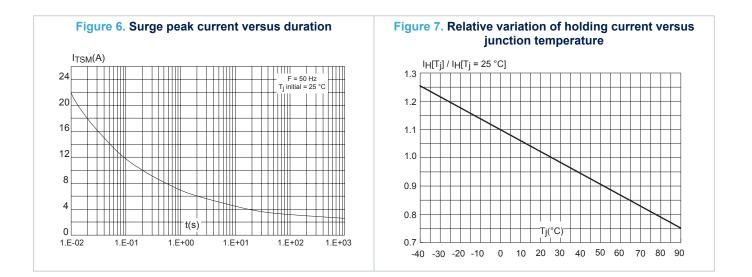

The LCP is particularly optimized for the new telecom applications such as the fiber in the loop, the WLL, the remote central office. In this case, the operating voltages are smaller than in the classical system. This makes the high voltage SLICs particularly suitable.

The schematics of Figure 5 give the most frequent topology used for these applications.
