1.3 说明

CC1310 器件是一款经济高效型超低功耗低于 1GHz 射频器件，由德州仪器 (TI)™ 倾力打造，属于 SimpleLink™ 微控制器 (MCU) 平台的组成部分。该平台包含 Wi-Fi®、低功耗 Bluetooth®、低于 1GHz、以太网、Zigbee®、Thread 和主机 MCU。所有这些器件均共用一个简单易用的通用开发环境，其中包含单个核心软件开发套件 (SDK) 和丰富的工具集。借助一次性集成的 SimpleLink 平台，用户可以将产品组合中的任何器件组合添加到自己的设计中，从而在设计要求变更时实现 100% 代码重用。有关更多信息，请访问 www.ti.com.cn/simplelink。

凭借极低的有源射频和 MCU 电流消耗以及灵活的低功耗模式，CC1310 器件可确保卓越的电池寿命，并能够在小型纽扣电池供电的情况下以及在能量采集应用中实现远距离工作。

CC1310 器件是 CC13xx 和 CC26xx 系列经济高效型超低功耗无线 MCU 中的一员，能够支持低于 1GHz 射频。CC1310 器件在一个支持多个物理层和射频标准的平台上将灵活的超低功耗射频收发器与强大的 48MHz Arm® Cortex®-M3 微控制器结合在一起。专用无线电控制器 (Cortex®-M0) 可处理存储在 ROM 或 RAM 中的低级射频协议命令，因而可确保超低功耗和灵活性。CC1310 器件在实现低功耗的同时不以牺牲射频性能为代价；CC1310 器件具有出色的灵敏度和稳健性（选择性和阻断性）性能。

CC1310 器件是高度集成的真正的单芯片解决方案，整合了完整的射频系统和片上直流/直流转换器。

传感器可由专用的超低功耗自主 MCU 以超低功耗方式进行处理（该 MCU 可配置为处理模拟和数字传感器），因此主 MCU (Arm® Cortex®-M3) 能够最大限度延长睡眠时间。

CC1310 器件的电源和时钟管理系统以及无线电系统需要采用特定配置并由软件处理才能正确运行，这已在 TI-RTOS 中实现。TI 建议将此软件框架用于该器件的全部应用开发过程。完整的 TI-RTOS 和设备驱动程序均有免费的源代码可供使用。

- Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- All voltage values are with respect to ground, unless otherwise noted.
- Including analog-capable DIO.
- Each pin is referenced to a specific V_{DDSn} (V_{DDS}, V_{DDS2} or V_{DDS3}). For a pin-to-V_{DDSn} mapping table, see [Table 6-3](#).

5.2 ESD Ratings

			VALUE	UNIT

		Charged device model (CDM), per JESD22-C101 ⁽²⁾	All pins	±500

- JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

5.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT	
Ambient temperature		−40	85	°C	
Operating supply voltage (V _{DDS})	For operation in battery-powered and 3.3-V systems (internal DC/DC can be used to minimize power consumption)	1.8	3.8	V	
Operating supply voltages (V _{DDS2} and V _{DDS3})		V _{DDS} < 2.7 V	1.8	3.8	V
Operating supply voltages (V _{DDS2} and V _{DDS3})		V _{DDS} ≥ 2.7 V	1.9	3.8	V
Rising supply voltage slew rate		0	100	mV/μs	
Falling supply voltage slew rate		0	20	mV/μs	
Falling supply voltage slew rate, with low-power flash setting ⁽¹⁾			3	mV/μs	
Positive temperature gradient in standby ⁽²⁾	No limitation for negative temperature gradient, or outside standby mode		5	°C/s	

- For small coin-cell batteries, with high worst-case end-of-life equivalent source resistance, a 22-μF V_{DDS} input capacitor must be used to ensure compliance with this slew rate.
- Applications using RCOSC_LF as sleep timer must also consider the drift in frequency caused by a change in temperature (see).

6 Detailed Description

6.1 Overview

节 1.4 shows a block diagram of the core modules of the CC13xx product family.

6.2 Main CPU

The CC1310 SimpleLink Wireless MCU contains an ARM Cortex-M3 (CM3) 32-bit CPU, which runs the application and the higher layers of the protocol stack.

The CM3 processor provides a high-performance, low-cost platform that meets the system requirements of minimal memory implementation and low-power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

The CM3 features include the following:

- 32-bit ARM Cortex-M3 architecture optimized for small-footprint embedded applications
- Outstanding processing performance combined with fast interrupt handling
- ARM Thumb[®]-2 mixed 16- and 32-bit instruction set delivers the high performance expected of a 32-bit ARM core in a compact memory size usually associated with 8- and 16-bit devices, typically in the range of a few kilobytes of memory for microcontroller-class applications:
 - Single-cycle multiply instruction and hardware divide
 - Atomic bit manipulation (bit-banding), delivering maximum memory use and streamlined peripheral control
 - Unaligned data access, enabling data to be efficiently packed into memory
- Fast code execution permits slower processor clock or increases sleep mode time
- Harvard architecture characterized by separate buses for instruction and data
- Efficient processor core, system, and memories
- Hardware division and fast digital-signal-processing oriented multiply accumulate
- Saturating arithmetic for signal processing
- Deterministic, high-performance interrupt handling for time-critical applications
- Enhanced system debug with extensive breakpoint and trace capabilities
- Serial wire trace reduces the number of pins required for debugging and tracing
- Migration from the ARM7[™] processor family for better performance and power efficiency
- Optimized for single-cycle flash memory use
- Ultra-low power consumption with integrated sleep modes
- 1.25 DMIPS per MHz

6.3 RF Core

The RF core is a highly flexible and capable radio system that interfaces the analog RF and baseband circuits, handles data to and from the system side, and assembles the information bits in a given packet structure.

The RF core can autonomously handle the time-critical aspects of the radio protocols, thus offloading the main CPU and leaving more resources for the user application. The RF core offers a high-level, command-based API to the main CPU.

The RF core supports a wide range of modulation formats, frequency bands, and accelerator features, which include the following:

- Wide range of data rates:
 - From 625 bps (offering long range and high robustness) to as high as 4 Mbps
- Wide range of modulation formats:
 - Multilevel (G) FSK and MSK
 - On-Off Keying (OOK) with optimized shaping to minimize adjacent channel leakage
 - Coding-gain support for long range
- Dedicated packet handling accelerators:
 - Forward error correction
 - Data whitening
 - 802.15.4g mode-switch support
 - Automatic CRC
- Automatic listen-before-talk (LBT) and clear channel assist (CCA)
- Digital RSSI
- Highly configurable channel filtering, supporting channel spacing schemes from 40 kHz to 4 MHz
- High degree of flexibility, offering a future-proof solution

The RF core interfaces a highly flexible radio, with a high-performance synthesizer that can support a wide range of frequency bands.

6.4 Sensor Controller

The Sensor Controller contains circuitry that can be selectively enabled in standby mode. The peripherals in this domain may be controlled by the Sensor Controller Engine, which is a proprietary power-optimized CPU. This CPU can read and monitor sensors or perform other tasks autonomously; thereby significantly reducing power consumption and offloading the main CM3 CPU.

A PC-based development tool called [Sensor Controller Studio](#) is used to write, test, and debug code for the Sensor Controller. The tool produces C driver source code, which the System CPU application uses to control and exchange data with the Sensor Controller. Typical use cases may be (but are not limited to) the following:

- Analog sensors using integrated ADC
- Digital sensors using GPIOs with bit-banged I²C or SPI
- Capacitive sensing
- Waveform generation
- Pulse counting
- Key scan
- Quadrature decoder for polling rotational sensors

The peripherals in the Sensor Controller include the following:

- The low-power clocked comparator can be used to wake the device from any state in which the comparator is active. A configurable internal reference can be used with the comparator. The output of the comparator can also be used to trigger an interrupt or the ADC.
- Capacitive sensing functionality is implemented through the use of a constant current source, a time-to-digital converter, and a comparator. The continuous time comparator in this block can also be used as a higher-accuracy alternative to the low-power clocked comparator. The Sensor Controller takes care of baseline tracking, hysteresis, filtering, and other related functions.
- The ADC is a 12-bit, 200-ksamples/s ADC with 8 inputs and a built-in voltage reference. The ADC can be triggered by many different sources, including timers, I/O pins, software, the analog comparator, and the RTC.
- The analog modules can be connected to up to eight different GPIOs (see [Table 6-1](#)).

The peripherals in the Sensor Controller can also be controlled from the main application processor.

(1) Depending on the package size, up to 15 pins can be connected to the Sensor Controller. Up to eight of these pins can be connected to analog modules.

6.5 Memory

The flash memory provides nonvolatile storage for code and data. The flash memory is in-system programmable.

The SRAM (static RAM) is split into two 4-KB blocks and two 6-KB blocks and can be used to store data and execute code. Retention of the RAM contents in standby mode can be enabled or disabled individually for each block to minimize power consumption. In addition, if flash cache is disabled, the 8-KB cache can be used as general-purpose RAM.

The ROM provides preprogrammed, embedded TI-RTOS kernel and Driverlib. The ROM also contains a bootloader that can be used to reprogram the device using SPI or UART.

6.6 Debug

The on-chip debug support is done through a dedicated cJTAG (IEEE 1149.7) or JTAG (IEEE 1149.1) interface.

6.7 Power Management

To minimize power consumption, the CC1310 device supports a number of power modes and power-management features (see [Table 6-2](#)).

Brown Out Detector (BOD)	Active	Active	Duty Cycled ⁽²⁾	Off	N/A
Power On Reset (POR)	Active	Active	Active	Active	N/A

(1) Not including RTOS overhead.

(2) The Brown Out Detector is disabled between recharge periods in STANDBY. Lowering the supply voltage below the BOD threshold between two recharge periods while in STANDBY may cause the BOD to lock the device upon wakeup until a Reset/POR releases it. To avoid this, it is recommended that STANDBY mode is avoided if there is a risk that the supply voltage (VDD5) may drop below the specified operating voltage range. For the same reason, it is also good practice to ensure that a power cycling operation, such as a battery replacement, triggers a Power-on-reset by ensuring that the VDD5 decoupling network is fully depleted before applying supply voltage again (for example, inserting new batteries). This restriction does not apply to CC1310 die revision B or later.

In active mode, the application CM3 CPU is actively executing code. Active mode provides normal operation of the processor and all of the peripherals that are currently enabled. The system clock can be any available clock source (see [Table 6-2](#)).

In idle mode, all active peripherals can be clocked, but the Application CPU core and memory are not clocked and no code is executed. Any interrupt event returns the processor to active mode.

In standby mode, only the always-on (AON) domain is active. An external wake-up event, RTC event, or Sensor Controller event is required to return the device to active mode. MCU peripherals with retention do not need to be reconfigured when waking up again, and the CPU continues execution from where it went into standby mode. All GPIOs are latched in standby mode.

In shutdown mode, the device is entirely turned off (including the AON domain and Sensor Controller), and the I/Os are latched with the value they had before entering shutdown mode. A change of state on any I/O pin defined as a *wake from shutdown pin* wakes up the device and functions as a reset trigger. The CPU can differentiate between reset in this way and reset-by-reset pin or POR by reading the reset status register. The only state retained in this mode is the latched I/O state and the flash memory contents.

The Sensor Controller is an autonomous processor that can control the peripherals in the Sensor Controller independent of the main CPU. This means that the main CPU does not have to wake up, for example to execute an ADC sample or poll a digital sensor over SPI, thus saving both current and wake-up time that would otherwise be wasted. The Sensor Controller Studio lets the user configure the Sensor Controller and choose which peripherals are controlled and which conditions wake up the main CPU.

6.8 Clock Systems

The CC1310 device supports two external and two internal clock sources.

A 24-MHz external crystal is required as the frequency reference for the radio. This signal is doubled internally to create a 48-MHz clock.

The 32.768-kHz crystal is optional. The low-speed crystal oscillator is designed for use with a 32.768-kHz watch-type crystal.

The internal high-speed RC oscillator (48-MHz) can be used as a clock source for the CPU subsystem.

The internal low-speed RC oscillator (32-kHz) can be used as a reference if the low-power crystal oscillator is not used.

The 32-kHz clock source can be used as external clocking reference through GPIO.

6.9 General Peripherals and Modules

The I/O controller controls the digital I/O pins and contains multiplexer circuitry to assign a set of peripherals to I/O pins in a flexible manner. All digital I/Os are interrupt and wake-up capable, have a programmable pullup and pulldown function, and can generate an interrupt on a negative or positive edge (configurable). When configured as an output, pins can function as either push-pull or open-drain. Five GPIOs have high-drive capabilities, which are marked in **bold** in [Section 4](#).

The SSIs are synchronous serial interfaces that are compatible with SPI, MICROWIRE, and TI's synchronous serial interfaces. The SSIs support both SPI master and slave up to 4 MHz.

The UART implements a universal asynchronous receiver and transmitter function. The UART supports flexible baud-rate generation up to a maximum of 3 Mbps.

Timer 0 is a general-purpose timer module (GPTM) that provides two 16-bit timers. The GPTM can be configured to operate as a single 32-bit timer, dual 16-bit timers, or as a PWM module.

Timer 1, Timer 2, and Timer 3 are also GPTMs; each timer is functionally equivalent to Timer 0.

In addition to these four timers, a separate timer in the RF core handles timing for RF protocols; the RF timer can be synchronized to the RTC.

The I2S interface is used to handle digital audio (for more information, see the [CC13x0, CC26x0 SimpleLink™ Wireless MCU Technical Reference Manual](#)).

The I²C interface is used to communicate with devices compatible with the I²C standard. The I²C interface can handle 100-kHz and 400-kHz operation, and can serve as both I²C master and I²C slave.

The TRNG module provides a true, nondeterministic noise source for the purpose of generating keys, initialization vectors (IVs), and other random number requirements. The TRNG is built on 24 ring oscillators that create unpredictable output to feed a complex nonlinear-combinatorial circuit.

The watchdog timer is used to regain control if the system fails due to a software error after an external device fails to respond as expected. The watchdog timer can generate an interrupt or a reset when a predefined time-out value is reached.

The device includes a direct memory access (μ DMA) controller. The μ DMA controller provides a way to offload data-transfer tasks from the CM3 CPU, thus allowing for more efficient use of the processor and the available bus bandwidth. The μ DMA controller can perform transfer between memory and peripherals. The μ DMA controller has dedicated channels for each supported on-chip module and can be programmed to automatically perform transfers between peripherals and memory when the peripheral is ready to transfer more data.

Some features of the μ DMA controller follow (this is not an exhaustive list):

- Highly flexible and configurable channel operation of up to 32 channels
- Transfer modes: memory-to-memory, memory-to-peripheral, peripheral-to-memory, and peripheral-to-peripheral
- Data sizes of 8, 16, and 32 bits

The AON domain contains circuitry that is always enabled, except when in shutdown mode (where the digital supply is off). This circuitry includes the following:

- The RTC can be used to wake the device from any state where it is active. The RTC contains three compare registers and one capture register. With software support, the RTC can be used for clock and calendar operation. The RTC is clocked from the 32-kHz RC oscillator or crystal. The RTC can also be compensated to tick at the correct frequency even when the internal 32-kHz RC oscillator is used instead of a crystal.
- The battery monitor and temperature sensor are accessible by software and provide a battery status indication as well as a coarse temperature measure.

6.10 Voltage Supply Domains

The CC1310 device can interface to two or three different voltage domains depending on the package type. On-chip level converters ensure correct operation as long as the signal voltage on each input/output pin is set with respect to the corresponding supply pin (VDDS, VDDS2, or VDDS3). [Table 6-3](#) lists the pin-to-VDDS mapping.

Table 6-3. Pin Function to VDDS Mapping Table

	Package		
	VQFN 7 × 7 (RGZ)	VQFN 5 × 5 (RHB)	VQFN 4 × 4 (RSM)
VDDS ⁽¹⁾	DIO 23–30 Reset_N	DIO 7–14 Reset_N	DIO 5–9 Reset_N
VDDS2	DIO 1–11	DIO 0–6 JTAG_TCKC JTAG_TMSC	DIO 0–4 JTAG_TCKC JTAG_TMSC
VDDS3	DIO 12–22 JTAG_TCKC JTAG_TMSC	NA	NA

(1) The VDDS_DCDC pin must always be connected to the same voltage as the VDDS pin.

6.11 System Architecture

Depending on the product configuration, the CC1310 device can function as a wireless network processor (WNP – a device running the wireless protocol stack, with the application running on a separate host MCU), or as a system-on-chip (SoC) with the application and protocol stack running on the ARM CM3 core inside the device.

In the first case, the external host MCU communicates with the device using SPI or UART. In the second case, the application must be written according to the application framework supplied with the wireless protocol stack.

8 器件和文档支持

TI 提供大量的开发工具。下面介绍用于评估器件性能、生成代码以及开发解决方案的工具和软件。

8.1 器件命名规则

为了标明产品开发周期的各个产品阶段，TI 为所有部件号和/或日期代码添加了前缀。每个器件都具有以下三个前缀/标识中的一个：X、P 或无（无前缀）（例如 CC1310 正在批量生产，因此未分配前缀/标识）。

器件开发进化流程：

- X** 试验器件不一定代表最终器件的电气规范标准并且不可使用生产组装流程。
- P** 原型器件不一定是最终芯片模型并且不一定符合最终电气标准规范。
- 无** 完全合格的芯片模型的生产版本。

生产器件已进行完全特性化，并且器件的质量和可靠性已经完全论证。TI 的标准保修证书适用。

预测显示原型器件（X 或者 P）的故障率大于标准生产器件。由于它们的预计的最终使用故障率仍未定义，德州仪器 (TI) 建议不要将这些器件用于任何生产系统。只有合格的产品器件将被使用。

TI 器件的命名规则还包括一个带有器件系列名称的后缀。这个后缀表示封装类型（例如 RGZ）。

要获得 CC1310 器件（采用 RSM (4mm x 4mm)、RHB (5mm x 5mm) 或 RGZ (7mm x 7mm) 封装类型）的订购部件号，请参见本文档的封装选项附录（TI 网站 www.ti.com），或者联系您的 TI 销售代表。
